7375. Improved 2G and 3G bands

Yahoo group: spectrumanalyzer (2011)
Date: 2011-01-01 22:00:24 UTC
From: Mark Burgin
Topic: 7375 Message: 7375
Attachments: 1 described; binary payloads are missing from this source WARC

Hi Everyone
I fully understand that the original design for the MSA had a 1GHz frequency limit and that the 2G and 3G bands were added on later "for free" just by some clever changes to the software and adjustments to the circuit topology. As such, it is to be expected that there are some small deficiencies with the operation of these bands, In particular, there are images at 21.4GHz offset in the 2G band, and the 3G band has a large spur at 2026.6MHz.
Please don't think I am being critical in any way of the design of the MSA since I appreciate that one of the key design goals was to make the device as cheap as possible while still achieving sufficent degree of usefulness. It does this admirably.
However, I wondered what would be needed to change the existing design so that it had "proper" 2G, 3G, and perhaps higher, bands. What I mean by "proper" is bands which have the same quality as the 1G band. ie freedom from large spurs and images. Has anyone given this any thought?
I am very inexperienced at RF design, but, for what it's worth, and to start off a discussion, here are my ideas (WHICH MIGHT BE UTTER RUBBISH, SO PLEASE DON'T MISTAKE ANY OF THE FOLLOWING FOR A GOOD DESIGN SUGGESTION).
My understanding is that the basic problem with the 3G band is that the 1st IF lies within the range of required LO frequencies and so leakage through the mixer when the LO is at 1013.3MHz causes the large spur. In the 2G band, the problem is that the 1st IF is too low (10.7MHz) which makes it impossible to separate the frequencies of interest from their image frequencies. In both cases, a different 1st IF would alleviate the problem.
A first IF which is just below 1GHz would cure both of these issues, however, the 1G band requires that the 1st IF is above 1GHz, otherwise an input signal which happens to be at the same frequency as the 1st IF would leak through the mixer and cause noise across the whole spectrum. It looks, therefore, that two different 1st IFs are required to support the three bands, but since the cavity filter is tuned to the 1013.3MHz, an additional cavity filter would be necessary along with the associated swiching arrangements. The cavity filter is bulky, time-consuming to make and quite expensive unless you happen to have all the materials to hand and so I wanted to avoid having to include another one in the system.
I wondered about the possiblilty of adding another mixer and PLO in front of MIXER 1 in the current design to create a new 1st IF (I call it IF0 from here on) that can be swicthed between a frequency just above 1GHz and just below 1GHz depending on the band. The exisiting MIXER 1 could then be used to convert either of the two different IF0 frequencies to 1013.3MHz as normal. I have attempted to show the arrangement in the attached pdf file (I hope my attachment works!).
For the 2G band, IF0 is set to 986.7MHz and the new PLO, PLO0 is swept from 1986.7MHz to 2986.7MHz. I appreciate that this is outside the capabilites of the current PLO and so a new design would be required. PLO1 (exisiting) is set to a fixed frequency of 2000MHz) which will convert IF0 to 1013.3MHz.
For the 3G band, IF0 is also set to 986.7MHz with its PLO swept from 1013.3MHz to 2013.3MHz. This can be done by the exisiting PLO1 design.
For the 1G band, two possibilities exist. PLO1 is not really needed for this mode since the new PLO0 could sweep from 1013.3MHz to 2013.3MHz so that the output from MIXER0 (the new mixer) could feed into the cavity filter directly. However, this would require some signal

switching to bypass MIXER1 when the 1G mode is selected. An alternative would be to sweep LO0 from 1018.7MHz to 2018.7MHz, creating an IF0 of 1018.7MHz. If PLO1 is set to 2032MHz, MIXER1 will output the required 1013.3MHz without any switching being required. I also considered making IF0 1013.3MHz in this band, with LO1 set to 2026.6 MHz, this also gives 1013.3MHz at the output of MIXER1 but I am not sure that I understand the mixing process well enough to be sure that all would work OK when the RF signal and IF signal are at the same frequency and the LO is at twice that frequency. Note that if the PLO1 frequencies shown are chosen (multiples of 4MHz), I think PLO1 could be driven from the 64MHz clock, freeing up DDS1 to be used to drive the new PLO0.
What are the difficulties with this arrangement? Well, I can see a few and I am sure there are many others that I can't see.

* Addional cost. Is it worth it for the small (hoped for) benefits? Probably not, but I am a bit of a purist. What if I want to look at a signal near 2026.6MHz? What if I want to look at a signal in the 2G band that is 21.4MHz above another signal? I know! How likely is that?

* In all modes there is an extra mixing stage introducing more phase noise and conversion loss. Will this be much of a problem? Since PLO1 does not need to sweep in frequency in this arrangement, I presume that it could be changed to improve its phase noise.

* The software would need to be changed extensively to support this arrangement.

* PLO0 needs to have a range from 1GHz to 3GHz. I don't think this can be achieved with a single VCO. Could anything be done to utilise the second harmonic of the 1GHz to 2GHz PLO in order to support the 2G range? Perhaps two VCOs could be used with some means of switching between them. Is switching the LOs any easier that swicthing in the direct signal path? Perhaps the LO that is not used can be powered down so that the switch's isolation is less of an issue.

* Does the ADE-11 mixer perform adeqately with a 3GHz LO signal?

* Are there better ways of accomplishng the same thing.
Comments anyone? Please feel free to shoot me down in flames.
Mark

Topic: 7375 Message: 7376

Hi Mark,
Nothing is ever Utter Rubbish, so don't hesitate to bring up new ideas. The MSA is an on-going, ever changing project. You have several good questions, and I would like to take a fair amount of time to think about them before throwing out quick answers. But I'll answer one quickie now.
 The ADE-11X should work quite well at 3 GHz on its LO and RF ports. Its IF port is the one that gets lousy above about 1100 MHz. Mixer 1 could be "flipped" so that its R port is used as the input to the MSA and its I port is sent to the Cavity Filter (or Mixer 2 during 2G). This arrangement would work quite well for .5 GHz to 3 GHz inputs.
 Other folks can comment on your suggestions while I mull them over.
Scotty

From: davidhooau
Topic: 7377 Message: 7377

Sam,

In your excellent ExpandedLogDetector2.pdf, and in your own MSA, you have used a 20dB IF2 amp with an AD8099. Do you have a schematic and PCB design available?

Many thanks,

davidh

7378. Wanted set of MSA Slim boards

Yahoo group: spectrumanalyzer (2011)
Date: 2011-01-02 14:51:10 UTC
From: Dale
Topic: 7378 Message: 7378

I saw the message from Bob that he does not have any more boards available.

Does anyone have a set of circuit boards for sale?

Are there any plans for another run of boards?

Thanks,

Dale / KB9JJA

I did build an AD8099 amp, which I chose because of excellent distortion performance. But I ended up going with the OPA847 with gain of about 28 dB. With op amps, you lose 6 dB from the voltage gain of the op amp itself, because of the series output resistor used to give a 50 ohm output. So the op amp itself needs V/V gain of over 30, which the OPA847 can do. It also has very low distortion.

I put the files at
<http://www.wetterlin.org/sam/SA/ExpandedLogDetect/IF2Amp_OPA847.zip>

You could also use the standard IF Amp, if you have already built it. Just put an attenuator between its two sections in order to reduce the total gain.

7380. Weird Crash--Don't use Desktop for Files

Yahoo group: spectrumanalyzer (2011)
Date: 2011-01-02 18:50:53 UTC
From: Sam
Topic: 7380 Message: 7380

I have narrowed down the cause of an occasional weird crash that I previously reported could occur when saving graph images. The crash occurs while the file dialog is open, if you hover over a file icon so as to open its tool tip. The first time through the dialog, there is no problem. The second time, you may crash (protection violation).

It took me a while to make the connection with tool tips. I was never intentionally trying to open tool tips; I would usually be thinking about what I wanted to do and would just happen to move the mouse over a file while thinking.

After considerable experimentation, and a lot of crashes, it appears to me that this crash only occurs when the target files (the ones you hover over) are on the desktop. That's where I would usually save image files and certain other files. It turns out that if you create a folder on the desktop and store the files in there, the crash does not occur. So I recommend not saving files directly on the desktop.

This crash occurs in both Win2000 and XP, and it turns out that it has been reported on the internet in other contexts, so it apparently is not a Liberty Basic issue. If all else fails, the ultimate solution would be to turn off tool tips.

There are a lot of good ideas in there. Whether it is worth the trouble depends on how much time you would spend in 2G and 3G. That one spur in 3G is not much of an issue unless you care about that specific frequency. The ghost images in 2G SA mode are OK if you look at narrow frequency ranges, though I suppose they would be irritating if you did a lot of 2G work.

Here's a possible alternative: I have an amplified LO3 output to use as the TG signal in 2G mode. It also is strong enough to be the LO of a mixer. In SA mode you don't need LO3, so you could use it to down-convert the target signals. For example, set it to 1 GHz to down-convert the 1-2 GHz range to 0-1GHz. Set it to 2GHz to down-convert the 2-3 GHz range to 0-1 GHz. Some filtering would also be required. You could even use this approach with 3-4 GHz, and higher by using harmonic mixing. All it takes is an external mixer with the appropriate frequency range. Low-pass filter the mixer output and run it into the MSA. The MSA would then operate as usual, but what it displays as 50 MHz would actually be 1050 MHz, or whatever.

You can create front-end compensation files for SA mode, which you would use to compensate for the frequency response of the down-converting mixer.

Sam W.

I see some post about the Atten Spectrum Analyzer AT5011.

and I see by the Specs that it was a display of 4 1/2 digits.

ex: 450.1, 450.2 and so on ... has anyone used an RF sampler and a Freq counter to get a finer tuning

ex: 450.1125, 450.2225 and so on

karl n2rld

The 5011 neeeds a climate controlled environment to be stable. It's an
obsolete design now - look for 6011.

If you czan find one cheap - fine but...

I do not have a complete set of boards available.

If interested, I do have two of the "Control Panel Miniboards". These include only the control board, the ADC, and the LD-8306 boards. They are Rev C 3-14-2010.

I paid $60.85 for three of them, I used one, and have two extras. I would like to get $15 each (I will ship USPS 1st class to the continental U.S. for that. Other locales, actual shipping charges would apply. E-mail me if interested.

It is likely that I may soon also have a couple extra of the LO2 miniboard (PLO, IF Amp, MCF, MXR, MO),

Info on the MSA "Miniboards" is at http://www.scottyspectrumanalyzer.com/msaexpress.html

I chose the miniboard service for a couple reasons. 1) there is less "slicing and dicing" than there would have been with a full panel. 2)By doing one mini-board at a time, it is not quite as intimidating as looking at one empty "full panel"

-Paul

Hi Sam

Thanks for the comments. I certainly take you point about whether or not it is worth the trouble. To be honest, I am exploring this more out of academic interest than through a real need to improve the performance for a practical purpose. The current MSA design is already good enough for 99.9% of all uses.

Your idea is certainly much simpler than mine, doesn't need many software changes and can easily be extended to higher frequencies. In fact, I considered the kind of arrangement you suggest but discounted it because I believe that there might be an image rejection issue.

When set to the 2G band (new LO of 1GHz), input signals just above 1GHz would have an image frequency that is just below 1GHz and so difficult to filter out. Of course, frequencies higher in the band will have images that are further and further away from the signal of interest. However, it would not be practical to provide filtering on the input that rejects the unwanted image frequencies across the whole 2G band but at least the image frequencies are always out-of-band so you won't see images of in-band signals.

In the scheme I described in my original post, I attempted to ensure that the unwanted image frequencies are always around 2GHz away from the signals of interest (since IF0 is always approx. 1GHz) resulting in a nearly 1GHz wide window in which an input filter could do its stuff. Whether or not the image frequency issue is important depends on what the signals are that you are looking at. If you know that there are no signals present in the image frequency range then everything works fine. On the other hand, if you are looking at a signal from an antenna, for example, then you can be less certain that you know what you are looking at if there is an un-rejected image frequency range.

I know I am being a perfectionist again and that's not really what the MSA is about, but I am curious to know how perfect it can be made to be.

Mark

Subject: [spectrumanalyzer] Re: Improved 2G and 3G bands

There are a lot of good ideas in there. Whether it is worth the trouble depends on how much time you would spend in 2G and 3G. That one spur in 3G is not much of an issue unless you care about that specific frequency. The ghost images in 2G SA mode are OK if you look at narrow frequency ranges, though I suppose they would be irritating if you did a lot of 2G work.

Here's a possible alternative: I have an amplified LO3 output to use as the TG signal in 2G mode. It also is strong enough to be the LO of a mixer. In SA mode you don't need LO3, so you could use it to down-convert the target signals. For example, set it to 1 GHz to

down-convert the 1-2 GHz range to 0-1GHz. Set it to 2GHz to down-convert the 2-3 GHz range to 0-1 GHz. Some filtering would also be required. You could even use this approach with 3-4 GHz, and higher by using harmonic mixing. All it takes is an external mixer with the appropriate frequency range. Low-pass filter the mixer output and run it into the MSA. The MSA would then operate as usual, but what it displays as 50 MHz would actually be 1050 MHz, or whatever.

You can create front-end compensation files for SA mode, which you would use to compensate for the frequency response of the down-converting mixer.

Sam W.

From: Sam
Topic: 7377 Message: 7387

Neal,
Without the resistor, the impedance seen from the non-inverting input would be two parallel 50 ohm resistances, or 25 ohms. The 15 ohm resistor increases this to 40 ohms. Some high frequency op amps will oscillate if the non-inverting input sees an impedance far from 50 ohms. I believe the 15 ohm resistor was actually necessary on the AD8099 design to prevent oscillation. I think my OPA847 design simply inherited the resistor; it may not actually be necessary.

I cheated a bit on my explanation of using LO3 to down-convert signals. I made the statement that some filtering would also be required. That filtering would actually require perfect brick walls if you create bands of 1 GHz each. In reality, you would need to make the bands a little smaller. For example, the base SA could run from LF to 1 GHz with no down-conversion. The next band could start with LO3=950 MHz (I think it will go that low with no problem.) That would show 1 GHz as 50 MHz, and 1950 MHz as 1 GHz. The LO3 of 950 MHz would also show 900 MHz as 50 MHz, so you need to filter that out. That means you have to filter out 900 MHz and below but pass 1 GHz and above, which is feasible. This makes the "2G" band run from 1 GHz to 1950 MHz, which you would display by setting the sweep from 50 MHz to 1 GHz.

(Having the lowest signal of the band show at 50 MHz also has the advantage that your high frequency down-converting mixer may well not like its IF to operate down to a couple of MHz.)

More likely, you would have an interest in some specific frequency range, such as 1.8-2.0 GHz. You could make up your own band with the frequencies of interest near the middle. So you could set LO3=1.5 GHz, which will convert 1.8 GHz to 300 MHz, as it would also do to 1.2 GHz. Separating 1.2 GHz from 1.8 GHz would be relatively easy.

It seems likely that the bulk of SA applications above 1 GHz would involve bands-of-interest of a couple hundred MHz at most, which makes the filtering not to difficult. Sure, it sometimes would be nice to view harmonics over a broad range. But for that application, the standard MSA without extra down-conversion works fine--the 2G ghost images are easy to sort out if you have harmonics spaced at, say, 200 MHz.

I haven't thought this through, but there may be a variation of your scheme where the existing LO3, used as the LO for a pre-mixer, is swept rather than being fixed. Or maybe there is a way to simultaneously sweep LO1 and LO3 in a useful way. I am only fixated on using the existing LO3 because it simplifies things considerably--LO3 is needed for VNA modes anyway, and is already connected to the control board, and in SA mode it otherwise just sits there doing nothing (unless you are using the signal generator or tracking generator).

7389. Version 116 beta

Yahoo group: spectrumanalyzer (2011)
Date: 2011-01-03 00:28:50 UTC
From: Sam
Topic: 7389 Message: 7389

I have posted the beta version of the 116 software in the files section:

<http://groups.yahoo.com/group/spectrumanalyzer/files/MSA_version116_4b_Beta.zip>

This has a number of bug fixes plus many new features that are described in the zip file. It includes the USB interface, though there are a couple changes needed for USB to control automated switches (other than the RBW switch).

My plan is to switch back to hardware mode, and experiment with the video filter switch and other automated switches. For the most part, I don't plan to alter the software other than to fix problems.

Sam W.

Hi Mark,
 After some reflection, let me respond to your comments.
Your assumptions are quite correct. For sure, both 2G and 3G MSA operations are not "proper" topology, they are "icing on the cake". The cake is 1G. For "proper" topologies, to minimize spurious, it would be best to have a stand-alone MSA for each band. Adding the Mixer 0 topology will work, but has the potential to introduce another magnitude of spurious. (Plus that added cost). In my honest opinion (and how I use an analyzer, it is not worth the cost/complexity.
 As pointed out, the 3G Band contains only a few obvious spurs (total "inop" when trying to look at an external signal at, or near 2026.6 Hz). However, I think it is a minor encumbrance when the rest of 3G is quite good. (All that icing with a small bare patch).

 2G in MSA has image frequencies completely across the band. Nobody in his right mind would design a Spectrum Analyzer with this topology. (VNA operation here is not affected). The user needs to understand that if he is looking for unknown signals, he cannot be immediately assured that a response is a normal or image signal. It would be nice for the MSA to do something automatically and say "the response you see is a normal signal" or "the response you see is an image signal". Until we (Sam and I) come up with something cool, the user can manually determine this ambiguity. Here are two ways it is done:
1. If your MSA has at least two Resolution Filters that are not the same frequency:
Example, Path 1 =10.7 MHz and Path 2 = 10.11 Mhz
a. In Path 1, you are scanning and see a signal at 1000 MHz.
b. Halt the sweep and change the sweep parameters to place the signal at the center of the graph (CF = 1000 MHz)
c. Change to Path 2 and sweep again.
d. If the signal remains in the center, it is normal signal at 1000 MHz.
e. If the signal disappears or moves, it is an image signal at 1021.4 MHz.

2. If you have only one Resolution Filter (at 10.7 MHz)
a. Go to the Hardware Configuration Manager and lie to it by adding a Path 2 at 10.701 Mhz. (1 KHz higher than your real Filter)
b. In Path 1, you are scanning and see a signal at 1000 MHz.

c. Halt the sweep and change the sweep parameters to place the signal at the center of the graph (CF = 1000 MHz)

d. Change to Path 2 and sweep again.
e. If the signal moves down in frequency by 1 KHz, it is normal signal at 1000 MHz.

f. If the signal moves up in frequency by 1 KHz, it is an image signal at 1021.4 MHz.
Sometimes it is ok to fool Mother Nature, or in this case, your MSA.

[Attachment(s) from Mark Burgin included below]

Hi EveryoneI fully understand that the original design for the MSA had a 1GHz frequency limit and that the 2G and 3G bands were added on later "for free" just by some clever changes to the software and adjustments to the circuit topology. As such, it is to be expected that there are some small deficiencies with the operation of these bands, In particular, there are images at 21.4GHz offset in the 2G band, and the 3G band has a large spur at 2026.6MHz. Please don't think I am being critical in any way of the design of the MSA since I appreciate that one of the key design goals was to make the device as cheap as possible while still achieving sufficent degree of usefulness. It does this admirably.However, I wondered what would be needed to change the existing design so that it had "proper" 2G, 3G, and perhaps higher, bands. What I mean by "proper" is bands which have the same quality as the 1G band. ie freedom from large spurs and images. Has anyone given this any thought?I am very inexperienced at RF design, but, for what it's worth, and to start off a discussion, here are my ideas (WHICH MIGHT BE UTTER RUBBISH, SO PLEASE DON'T MISTAKE ANY OF THE FOLLOWING FOR A GOOD DESIGN SUGGESTION). My understanding is that the basic problem with the 3G band is that the 1st IF lies within the range of required LO frequencies and so leakage through the mixer when the LO is at 1013.3MHz causes the large spur. In the 2G band, the problem is that the 1st IF is too low (10.7MHz) which makes it impossible to separate the frequencies of interest from their image frequencies. In both cases, a different 1st IF would alleviate the problem. A first IF which is just below 1GHz would cure both of these issues, however, the 1G band requires that the 1st IF is above 1GHz, otherwise an input signal which happens to be at the same frequency as the 1st IF would leak through the mixer and cause noise across the whole spectrum. It looks, therefore, that two different 1st IFs are required to support the three bands, but since the cavity filter is tuned to the 1013.3MHz, an additional cavity filter would be necessary along with the associated swiching arrangements. The cavity filter is bulky, time-consuming to make and quite expensive unless you happen to have all the materials to hand and so I wanted to avoid having to include another one in the system.I wondered about the possiblilty of adding another mixer and PLO in front of MIXER 1 in the current design to create a new 1st IF (I call it IF0 from here on) that can be swicthed between a frequency just above 1GHz and just below 1GHz depending on the band. The exisiting MIXER 1 could then be used to convert either of the two different IF0 frequencies to 1013.3MHz as normal. I have attempted to show the arrangement in the attached pdf file (I hope my attachment works!).For the 2G band, IF0 is set to 986.7MHz and the new PLO, PLO0 is swept from 1986.7MHz to 2986.7MHz. I appreciate that this is outside the capabilites of the current PLO and so a new design would be required. PLO1 (exisiting) is set to a fixed frequency of 2000MHz) which will convert IF0 to 1013.3MHz.For the 3G band, IF0 is also set to 986.7MHz with its PLO swept from 1013.3MHz to 2013.3MHz. This can be done by the exisiting PLO1 design.For the 1G band, two possibilities exist. PLO1 is not really needed for this mode since the new PLO0 could sweep from 1013.3MHz to 2013.3MHz so that the output from MIXER0 (the new mixer) could feed into the cavity filter directly. However, this would require some signal switching to bypass MIXER1 when the 1G mode is selected. An alternative would be to sweep LO0 from 1018.7MHz to 2018.7MHz, creating an IF0 of 1018.7MHz. If PLO1 is set to 2032MHz, MIXER1 will output the required 1013.3MHz without any switching being required. I also considered making IF0 1013.3MHz in this band, with LO1 set to 2026.6 MHz, this also gives 1013.3MHz at the output of MIXER1 but I am not sure that I understand the mixing

process well enough to be sure that all would work OK when the RF signal and IF signal are at the same frequency and the LO is at twice that frequency. Note that if the PLO1 frequencies shown are chosen (multiples of 4MHz), I think PLO1 could be driven from the 64MHz clock, freeing up DDS1 to be used to drive the new PLO0.What are the difficulties with this arrangement? Well, I can see a few and I am sure there are many others that I can't see.· Addional cost. Is it worth it for the small (hoped for) benefits? Probably not, but I am a bit of a purist. What if I want to look at a signal near 2026.6MHz? What if I want to look at a signal in the 2G band that is 21.4MHz above another signal? I know! How likely is that?· In all modes
there is an extra mixing stage introducing more phase noise and conversion loss. Will this be much of a problem? Since PLO1 does not need to sweep in frequency in this arrangement, I presume that it could be changed to improve its phase noise. · The software would need to be changed extensively to support this arrangement.· PLO0 needs to have a range from 1GHz to 3GHz. I don't think this can be achieved with a single VCO. Could anything be done to utilise the second harmonic of the 1GHz to 2GHz PLO in order to support the 2G range? Perhaps two VCOs could be used with some means of switching between them. Is switching the LOs any easier that swicthing in the direct signal path? Perhaps the LO that is not used can be powered down so that the switch's isolation is less of an issue.· Does the ADE-11 mixer perform adeqately with a 3GHz LO signal?· Are there better ways of
accomplishng the same thing.Comments anyone? Please feel free to shoot me down in flames.Mark

Scotty
  Recently, Dale is looking for a set of board. I have several sets of MSA boards, which might be latest rev, I ordered last May. I did not use them because during the board ordering, I bought another set with some components on(some one did a half way work, and wanted to quit).
  Do you mind if I sell my boards to your MAS yahoo members?
Regards
Lin

Hi Lin,
 As you have found, shielding is very important. The MSA may be an inexpensive solution to a commercial SA, but it is just as sensitive. Stray signals and noise entering the modules are troublesome. You might relay to the group page what you have accomplished in your study of noise.

Hi Lin,
 This is one of the nice things about Group boards. Sharing ideas and selling extra materials.

Scotty
  Recently, Dale is looking for a set of board. I have several sets of MSA boards, which might be latest rev, I ordered last May. I did not use them because during the board ordering, I bought another set with some components on(some one did a half way work, and wanted to quit).
  Do you mind if I sell my boards to your MAS yahoo members?
Regards
Lin

Hi Lin,
 As you have found, shielding is very important. The MSA may be an inexpensive solution to a commercial SA, but it is just as sensitive. Stray signals and noise entering the modules are troublesome. You might relay to the group page what you have accomplished in your study of noise.

Scotty
Finally, my MSA noise floor (the baseline) calculated number is very close to what I see on the MSA screen.
The calculated noise floor at log detector input should be around -137dBm (1Hz), I measured this number with my commercial SA, I got same number. With the 1kHz RBW filter, the MSA should see a -107dBm baseline. Now I get this baseline at -108dBm, which is very close to the calculation.

What I did is that put the fence and lid for mixer 1, mixer 2, IFA (my log detector was shielded before), after that the spurs were gone, and I did a coarse cal between -100dBm and -108dBm, with step of 2dB. After that it works very well.
The commercial SA I am using, if I use 1KHz RBW filter, can reach -110 to -113dBm. We are not far away from the commercial SA. With Sam's expended log detector, the noise floor at log detector input would drop to -149dBm (1Hz), and the MSA baseline, with 1kHz RBW filter, should be -149+30 = -119dBm (actually
number Sam got -120dBm baseline), which is better than the commercial SA.
Thanks
Lin

Your "overall gain" of the MSA is not a factor in noise floor determination. Only the gain from the input of the IF Amp to the input of the Log Detector is what is important. The IF Amp gain should be +40 dB, +/- 2 dB. The insertion loss of the Resolution bandpass filter must be subtracted to get the real gain from the input of the IF Amp to the input of the Log Detector.

Scotty and Sam
I totally accept that there is very little practical reason to change anything in order to cover the "the small bare patch", and that the 21.4MHz images in 2G mode are just an inconvenience rather than a real problem. I like the idea of fiddling with the resoution filter centre frequency to determine if a signal is real or an image. For nearly all members of the group, it would not be worth the effort to change anything.
However I might still play with the ideas further myself, but without wasting any more of the group's time. Of course, if I come up with a great idea that costs no money and needs no software changes, I will report back! I'm an optimist!
Thanks very much for taking the time to respond. I appreciate that the nature of my post meant that it was not posible to dash off a quick response and that you both had to use up some of your valuable time writing your replies.
Mark

Subject: Re: [spectrumanalyzer] Improved 2G and 3G bands

Hi Mark,
After some reflection, let me respond to your comments.
Your assumptions are quite correct. For sure, both 2G and 3G MSA operations are not "proper" topology, they are "icing on the cake". The cake is 1G. For "proper" topologies, to minimize spurious, it would be best to have a stand-alone MSA for each band. Adding the Mixer 0 topology will work, but has the potential to introduce another magnitude of spurious. (Plus that added cost). In my honest opinion (and how I use an analyzer, it is not worth the cost/complexity.
As pointed out, the 3G Band contains only a few obvious spurs (total "inop" when trying to look at an external signal at, or near 2026.6 Hz). However, I think it is a minor encumbrance when the rest of 3G is quite good. (All that icing with a small bare patch).

2G in MSA has image frequencies completely across the band. Nobody in his right mind would design a Spectrum Analyzer with this topology. (VNA operation here is not affected). The user needs to understand that if he is looking for unknown signals, he cannot be immediately assured that a response is a normal or image signal. It would be nice for the MSA to do something automatically and say "the response you see is a normal signal" or "the response you see is an image signal". Until we (Sam and I) come up with something cool, the user can manually determine this ambiguity. Here are two ways it is done:
1. If your MSA has at least two Resolution Filters that are not the same frequency:
Example, Path 1 =10.7 MHz and Path 2 = 10.11 Mhz
a. In Path 1, you are scanning and see a signal at 1000 MHz.
b. Halt the sweep and change the sweep parameters to place the signal at the center of the graph (CF = 1000 MHz)
c. Change to Path 2 and sweep again.
d. If the signal remains in the center, it is normal signal at 1000 MHz.

e. If the signal disappears or moves, it is an image signal at 1021.4 MHz.

2. If you have only one Resolution Filter (at 10.7 MHz)
a. Go to the Hardware Configuration Manager and lie to it by adding a Path 2 at 10.701 Mhz. (1 KHz higher than your real Filter)
b. In Path 1, you are scanning and see a signal at 1000 MHz.
c. Halt the sweep and change the sweep parameters to place the signal at the center of the graph (CF = 1000 MHz)
d. Change to Path 2 and sweep again.
e. If the signal moves down in frequency by 1 KHz, it is normal signal at 1000 MHz.
f. If the signal moves up in frequency by 1 KHz, it is an image signal at 1021.4 MHz.
Sometimes it is ok to fool Mother Nature, or in this case, your MSA.

Hi Everyone

I fully understand that the original design for the MSA had a 1GHz frequency limit and that the 2G and 3G bands were added on later "for free" just by some clever changes to the software and adjustments to the circuit topology. As such, it is to be expected that there are some small deficiencies with the operation of these bands, In particular, there are images at 21.4GHz offset in the 2G band, and the 3G band has a large spur at 2026.6MHz. Please don't think I am being critical in any way of the design of the MSA since I appreciate that one of the key design goals was to make the device as cheap as possible while still achieving sufficent degree of usefulness. It does this admirably.

However, I wondered what would be needed to change the existing design so that it had "proper" 2G, 3G, and perhaps higher, bands. What I mean by "proper" is bands which have the same quality as the 1G band. ie freedom from large spurs and images. Has anyone given this any thought?

I am very inexperienced at RF design, but, for what it's worth, and to start off a discussion, here are my ideas (WHICH MIGHT BE UTTER RUBBISH, SO PLEASE DON'T MISTAKE ANY OF THE FOLLOWING FOR A GOOD DESIGN SUGGESTION).

My understanding is that the basic problem with the 3G band is that the 1st IF lies within the range of required LO frequencies and so leakage through the mixer when the LO is at 1013.3MHz causes the large spur. In the 2G band, the problem is that the 1st IF is too low (10.7MHz) which makes it impossible to separate the frequencies of interest from their image frequencies. In both cases, a different 1st IF would alleviate the problem.

A first IF which is just below 1GHz would cure both of these issues, however, the 1G band requires that the 1st IF is above 1GHz, otherwise an input signal which happens to be at the same frequency as the 1st IF would leak through the mixer and cause noise across the whole spectrum. It looks, therefore, that two different 1st IFs are required to support the three bands, but since the cavity filter is tuned to the 1013.3MHz, an additional cavity

filter would be necessary along with the associated swiching arrangements. The cavity filter is bulky, time-consuming to make and quite expensive unless you happen to have all the materials to hand and so I wanted to avoid having to include another one in the system.

I wondered about the possiblilty of adding another mixer and PLO in front of MIXER 1 in the current design to create a new 1st IF (I call it IF0 from here on) that can be swicthed between a frequency just above 1GHz and just below 1GHz depending on the band. The exisiting MIXER 1 could then be used to convert either of the two different IF0 frequencies to 1013.3MHz as normal. I have attempted to show the arrangement in the attached pdf file (I hope my attachment works!).

For the 2G band, IF0 is set to 986.7MHz and the new PLO, PLO0 is swept from 1986.7MHz to 2986.7MHz. I appreciate that this is outside the capabilites of the current PLO and so a new design would be required. PLO1 (exisiting) is set to a fixed frequency of 2000MHz) which will convert IF0 to 1013.3MHz.

For the 3G band, IF0 is also set to 986.7MHz with its PLO swept from 1013.3MHz to 2013.3MHz. This can be done by the exisiting PLO1 design.

For the 1G band, two possibilities exist. PLO1 is not really needed for this mode since the new PLO0 could sweep from 1013.3MHz to 2013.3MHz so that the output from MIXER0 (the new mixer) could feed into the cavity filter directly. However, this would require some signal switching to bypass MIXER1 when the 1G mode is selected. An alternative would be to sweep LO0 from 1018.7MHz to 2018.7MHz, creating an IF0 of 1018.7MHz. If PLO1 is set to 2032MHz, MIXER1 will output the required 1013.3MHz without any switching being required. I also considered making IF0 1013.3MHz in this band, with LO1 set to 2026.6 MHz, this also gives 1013.3MHz at the output of MIXER1 but I am not sure that I understand the mixing process well enough to be sure that all would work OK when the RF signal and IF signal are at the same frequency and the LO is at twice that frequency. Note that if the PLO1 frequencies shown are chosen (multiples of 4MHz), I think PLO1 could be driven from the 64MHz clock, freeing up DDS1 to be used to drive the new PLO0.

What are the difficulties with this arrangement? Well, I can see a few and I am sure there are many others that I can't see.

* Addional cost. Is it worth it for the small (hoped for) benefits? Probably not, but I am a bit of a purist. What if I want to look at a signal near 2026.6MHz? What if I want to look at a signal in the 2G band that is 21.4MHz above another signal? I know! How likely is that?

* In all modes there is an extra mixing stage introducing more phase noise and conversion loss. Will this be much of a problem? Since PLO1 does not need to sweep in frequency in this arrangement, I presume that it could be changed to improve its phase noise.

* The software would need to be changed extensively to support this arrangement.

* PLO0 needs to have a range from 1GHz to 3GHz. I don't think this can be achieved with a single VCO. Could anything be done to utilise the second harmonic of the 1GHz to 2GHz PLO in order to support the 2G range? Perhaps two VCOs could be used with some means of switching between them. Is switching the LOs any easier that swicthing in the direct signal path? Perhaps the LO that is not used can be powered down so that the switch's isolation is less of an issue.

* Does the ADE-11 mixer perform adeqately with a 3GHz LO signal?

* Are there better ways of accomplishng the same thing.

Comments anyone? Please feel free to shoot me down in flames.

Mark

Hi Mark,
 I like great ideas. Rarely, do they cost nothing and require no software changes. However, do not let that dissuade you. We can always decide if the cost/performance of an idea is valuable and make decisions accordingly. This is how the changes are made to the MSA and the project will continue to evolve.

The cavity filter is bulky, time-consuming to make and quite expensive unless you happen to have all the materials to hand and so I wanted to avoid having to include another one in the system.I wondered about the possiblilty of adding another mixer and PLO in front of MIXER 1 in the current design to create a new 1st IF (I call it IF0 from here on) that can be swicthed between a frequency just above 1GHz and just below 1GHz depending on the band. The exisiting MIXER 1 could then be used to convert either of the two different IF0 frequencies to 1013.3MHz as normal. I have attempted to show the arrangement in the attached pdf file (I hope my attachment works!).For the 2G band, IF0 is set to 986.7MHz and the new PLO, PLO0 is swept from 1986.7MHz to 2986.7MHz. I appreciate that this is outside the capabilites of the current PLO and so a new design would be required. PLO1 (exisiting) is set to a fixed frequency of 2000MHz) which will convert IF0 to 1013.3MHz.For the 3G band, IF0 is also set to 986.7MHz with its PLO swept from 1013.3MHz to 2013.3MHz. This can be done by the exisiting PLO1 design.For the 1G band, two possibilities exist. PLO1 is not really needed for this mode since the new PLO0 could sweep from 1013.3MHz to 2013.3MHz so that the output from MIXER0 (the new mixer) could feed into the cavity filter directly. However, this would require some signal switching to bypass MIXER1 when the 1G mode is selected. An alternative would be to sweep LO0 from 1018.7MHz to 2018.7MHz, creating an IF0 of 1018.7MHz. If PLO1 is set to 2032MHz, MIXER1 will output the required 1013.3MHz without any switching being required. I also considered making IF0 1013.3MHz in this band, with LO1 set to 2026.6 MHz, this also gives 1013.3MHz at the output of MIXER1 but I am not sure that I understand the mixing process well enough to be sure that all would work OK when the RF signal and IF signal are at the same frequency and the LO is at twice that frequency. Note that if the PLO1 frequencies shown are chosen (multiples of 4MHz), I think PLO1 could be driven from the 64MHz clock, freeing up DDS1 to be used to drive the new PLO0.What are the difficulties with this arrangement? Well, I can see a few and I am sure there are many others that I can't see.· Addional cost. Is it worth it for the small (hoped for) benefits? Probably not, but I am a bit of a purist. What if I want to look at a signal near 2026.6MHz? What if I want to look at a signal in the 2G band that is 21.4MHz above another signal? I know! How likely is that?· In all modes there is an extra mixing stage introducing more phase noise and conversion loss. Will this be much of a problem? Since PLO1 does not need to sweep in frequency in this arrangement, I presume that it could be changed to improve its phase noise. · The software would need to be changed extensively to support this arrangement.· PLO0 needs to have a range from 1GHz to 3GHz. I don't think this can be achieved with a single VCO. Could anything be done to utilise the second harmonic of the 1GHz to 2GHz PLO in order to support the 2G range? Perhaps two VCOs could be used with some means of switching between them. Is switching the LOs any easier that swicthing in the direct signal path? Perhaps the LO that is not used can be powered down so that the switch's isolation is less of an issue.· Does the ADE-11 mixer perform adeqately with a 3GHz LO signal?· Are there better ways of accomplishng the same thing.Comments anyone? Please feel free to shoot me down in flames.Mark

7396. Re: Improved 2G and 3G bands

Mark's post makes me undstand why HP8558B, a 1.5GHz SA, uses 2050MHz cavity filter. It's first LO runs from 2050 to 3550MHz.
To design a 3GHz SA without and spurs, we might need a LO above 6GHz, which is too difficult for a home made SA.
Maybe, we can design a 2.1GHz SA, some IC can provide 4.3GHz as LO with decent phase noise. the IC costs about $25. To do that, we need to redesign cavity filter to be 2050MHz or so, and find a first mixer which can work up to 4.3GHz. I think we have to add several switchs to switch the band... It would ba a lot of work.

Of course, if we had a 1.5 GHz SA, it would turn out that it would have its own "2G" band that could extend its range if you accept ghost images. Then we could think about raising the first IF to fix that 2G band, etc.

To me, having a basic 1 GHz 1G band, with a 2G band that has ghost images and a very usable 3G band, is pretty good. Especially since you can extend the range with a front-end down-mixer. Heck, if you have a stable 10 GHz signal source and a suitable mixer and band pass filter, you can bring the 10-11 GHz range down to 0-1 GHz and take a look at it.

From: inlinebeginner
Topic: 7375 Message: 7398

We might want to design a front end module with Sam's idea, i.e use mixer as band selector.

For 1G band, we use MSA as is.

For 2G band, we kick in the mixer, and set the LO to 2GHz, when input signal changes from 1GHz to 2GHz, the IF lower image will be from 1GHz(=2GHz-1GHz) to 0Hz (2GHz -2GHz). The higher image (LO + Input) is above 2GHz, and can be filtered out with a 1GHz LPF. This requires software change to refenct the mirrored frequency.

For 3G band, we still kink in the mixer, and set the LO to 3GHz. when input signal changes from 2GHz to 3GHz, the IF output will change from 1GHz to 0 Hz.

For 4G band..., As the IC (contains PLL, VCO and Mixer) can go up to 4.3GHz, therefore, we have a 4G band. Just set the LO to 4GHz. same thing. At the band boundary, it could have small problem, because the mixer1 can not really work down to 0Hz, this can be done by set the LO 1MHz a little bit higher, i.e. at 2.001GHz, 3.001GHz, 4.001GHz.

The drawback of this method is that the noise floor will be raised several dB, therefore, we may need a 10dB LNA in front of mixer.
Does this work?

> > > Date: Saturday, January 1, 2011, 4:00 PMÂ Hi EveryoneI fully understand that the original design for the MSA had a 1GHz frequency limit and that the 2G and 3G bands were added on later "for free" just by some clever changes to the software and adjustments to the circuit topology.Â As such, it is to be expected that there are some small deficiencies with the operation of these bands,Â In particular, there are images at 21.4GHz offset in the 2G band, and the 3G band has a large spur at 2026.6MHz.Â Please don't think I am being critical in any way of the design of the MSA since I appreciate that

one of the key design goals was to make the device as cheap as possible while still achieving sufficent degree of usefulness.Â It does this admirably.However, I wondered what would be needed to change the existing design so that it had "proper" 2G, 3G, and perhaps higher, bands.Â What I mean by "proper" is bands which Â have the same quality as the 1G band. ie
> > > freedom from large spurs and images.Â Has anyone given this any thought?I am very inexperienced at RF design, but, for what it's worth, and to start off a discussion, here are my ideas (WHICH MIGHT BE UTTER RUBBISH, SO PLEASE DON'T MISTAKE ANY OF THE FOLLOWING FOR A GOOD DESIGN SUGGESTION).Â My understanding is that the basic problem with the 3G band is that the 1st IF lies within the range of required LO frequencies and so leakage through the mixer when the LO is at 1013.3MHz causes the large spur.Â In the 2G band, the problem is that the 1st IF is too low (10.7MHz) which makes it impossible to separate the frequencies of interest from their image frequencies.Â In both cases, a different 1st IF would alleviate the problem.Â A first IF which is just below 1GHz would cure both of these issues, however, the 1G band requires that the 1st IF is above 1GHz, otherwise an input signal which happens to be at the same frequency as the 1st IF would leak
> > > through the mixer and cause noise across the whole spectrum.Â It looks, therefore, that two different 1st IFs are required to support the three bands, but since the cavity filter is tuned to the 1013.3MHz, an additional cavity filter would be necessary along with the associated swiching arrangements.Â The cavity filter is bulky, time-consuming to make and quite expensive unless you happen to have all the materials to hand and so I wanted to avoid having to include another one in the system.I wondered about the possiblilty of adding another mixer and PLO in front of MIXER 1 in the current design to create a new 1st IF (I call it IF0 from here on) that can be swicthed between a frequency just above 1GHz and just below 1GHz depending on the band.Â The exisiting MIXER 1 could then be used to convert either of the two different IF0 frequencies to 1013.3MHz as normal.Â I have attempted to show the arrangement in the attached pdf file (I hope my attachment
> > > works!).For the 2G band, IF0 is set to 986.7MHz and the new PLO, PLO0 is swept from 1986.7MHz to 2986.7MHz.Â I appreciate that this is outside the capabilites of the current PLO and so a new design would be required.Â PLO1 (exisiting) is set to a fixed frequency of 2000MHz) which will convert IF0 to 1013.3MHz.For the 3G band, IF0 is also set to 986.7MHz with its PLO swept from 1013.3MHz to 2013.3MHz.Â This can be done by the exisiting PLO1 design.For the 1G band, two possibilities exist.Â PLO1 is not really needed for this mode since the new PLO0 could sweep from 1013.3MHz to 2013.3MHz so that the output from MIXER0 (the new mixer) could feed into the cavity filter directly.Â However, this would require some signal switching to bypass MIXER1 when the 1G mode is selected.Â An alternative would be to sweep LO0 from 1018.7MHz to 2018.7MHz, creating an IF0 of 1018.7MHz.Â If PLO1 is set to 2032MHz, MIXER1 will output the required 1013.3MHz without any
> > > switching being required.Â I also considered making IF0 1013.3MHz in this band, with LO1 set to 2026.6 MHz, this also gives 1013.3MHz at the output of MIXER1 butÂ I am not sure that I understand the mixing process well enough to be sure that all would work OK when the RF signal and IF signal are at the same frequency and the LO is at twice that frequency.Â Note that if the PLO1 frequencies shown are chosen (multiples of 4MHz), I think PLO1 could be driven from the 64MHz clock, freeing up DDS1 to be used to drive the new PLO0.What are the difficulties with this arrangement?Â Well, I can see a few and I am sure there are many others that I can't see.Â·Â Â Â Â Â Â Â Â Addional cost.Â Is it worth it for the small (hoped for) benefits?Â Probably not, but I am a bit of a purist.Â What if I want to look at a signal near 2026.6MHz? Â What if I want to look at a signal in the 2G band that is 21.4MHz above another signal?Â I know! How likely is
> > > that?Â·Â Â Â Â Â Â Â Â Â In all modes there is an extra mixing stage introducing more

phase noise and conversion loss.Â Will this be much of a problem?Â Since PLO1 does not need to sweep in frequency in this arrangement, I presume that it could be changed to improve its phase noise. Â·Â Â Â Â Â Â Â Â The software would need to be changed extensively to support this arrangement.Â·Â Â Â Â Â Â Â Â PLO0 needs to have a range from 1GHz to 3GHz.Â I don't think this can be achieved with a single VCO.Â Could anything be done to utilise the second harmonic of the 1GHz to 2GHz PLO in order to support the 2G range? Â Â Perhaps two VCOs could be used with some means of switching between them.Â Is switching the LOs any easier that swicthing in the direct signal path?Â Perhaps the LO that is not used can be powered down so that the switch's isolation is less of an issue.Â·Â Â Â Â Â Â Â Â Does the ADE-11 mixer perform adeqately with a 3GHz LO
> > > signal?Â·Â Â Â Â Â Â Â Â Are there better ways of accomplishng the same thing.Comments anyone?Â Please feel free to shoot me down in flames.Mark Â

Hi Lin
Unfortunately, the image frequency at the input is always twice the IF away from the signal of interest. Since the IF goes from 0Hz to 1GHz in your scheme, the image frequency will be between 0Hz and 2GHz away from the signal of interest. For example, with the LO at 2GHz, a signal at 1.999GHz will convert to an IF of 1MHz (2000 - 1999 = 1). Unfortunatly, a signal at 2.001GHz (which is out of band but might still be present on the input) will also convert to 1MHz (1999 - 2000 = -1. The - sign is irrelevant since this is just a phase change). It would not be possible to design a filter that goes on the input that passes 1999MHz but rejects 2001MHz. Your spectrum analyser with a 2GHz LO would display the 1-2GHz and 2-3GHz spectrums simultaneously, much like the current design displays 0-1GHz and 2-3GHz signals simultaneously. Of course this is only a problem if out-of-band signals might be present on the input but this is often the case.
To avoid this issue, it is important that the IF is as high as possible since this creates a gap in which a filter on the input can roll off the response to the unwanted image frequencies. With the current MSA design with its 1.0133GHz 1st IF, filters could be placed on the input to pass 0-1GHz and reject 2-3GHz and vice-versa so that the 1G band and the 3G bands could be displayed separately if required. This is why I kept the 1st IF near to 1GHz in my scheme.
Mark

Subject: [spectrumanalyzer] Re: Improved 2G and 3G bands

We might want to design a front end module with Sam's idea, i.e use mixer as band selector.

For 1G band, we use MSA as is.

For 2G band, we kick in the mixer, and set the LO to 2GHz, when input signal changes from 1GHz to 2GHz, the IF lower image will be from 1GHz(=2GHz-1GHz) to 0Hz (2GHz -2GHz). The higher image (LO + Input) is above 2GHz, and can be filtered out with a 1GHz LPF. This requires software change to refenct the mirrored frequency.

For 3G band, we still kink in the mixer, and set the LO to 3GHz. when input signal changes from 2GHz to 3GHz, the IF output will change from 1GHz to 0 Hz.

For 4G band..., As the IC (contains PLL, VCO and Mixer) can go up to 4.3GHz, therefore, we have a 4G band. Just set the LO to 4GHz. same thing. At the band boundary, it could have small problem, because the mixer1 can not really work down to 0Hz, this can be done by set the LO 1MHz a little bit higher, i.e. at 2.001GHz, 3.001GHz, 4.001GHz.

The drawback of this method is that the noise floor will be raised several dB, therefore, we may need a 10dB LNA in front of mixer.
Does this work?
Lin

7400. Directional Couplers

Yahoo group: spectrumanalyzer (2011)
Date: 2011-01-05 00:11:01 UTC
From: Sam
Topic: 6702 Message: 7400

A directional coupler can make a simple bridge for the MSA in Reflection Mode. Some ZEDC-15-2B (1-1000 MHz) couplers are available on eBay, for $14.99, with free shipping:

http://cgi.ebay.com/Mini-Circuits-Directional-Coupler-ZEDC-15-2B-1-1000MHz-/270648790996?pt=LH_DefaultDomain_0&hash=item3f03eccfd4

These are Minicircuits devices packed in very small metal boxes with SMA connectors. I bought another type of MCL coupler and tested it; the results were disappointing and nowhere near MCL's datasheet graphs. But I bought a ZEDC-15-2B from this seller and tested its directivity, which matched the datasheet very well. The directivity ranges from near 70 dB at 1 MHz to 25 dB at 500 MHz and 18 dB at 1 GHz. 70 dB is phenomenal; 25 dB is good and 18 dB is very usable.

For a general purpose bridge, at this size and cost the ZEDC is hard to beat.

There are also other offerings on eBay for this coupler. One of them is priced over $300, which is completely insane, so be careful which one you sign up for.

Sam W.

Mark
You are right, the boundary will have problems to process. I hope someone can figure out a software way to calculate the boundary.
In the real world, if I want to measure a 40MHz bandwidth spectrum at 12GHz, and we only have a 3GHz SA, what do we do? Use a mixer and LO. If the spectrum is at the boundary, we have to adjust the LO frequency to move the spectrum away the boundary. If we can manully to do this, we might be able to let computer do it automatically when the condition can be met.
Anyway, this is a good discussion. It makes us think about something that we did not pay attention.
Thanks
Lin

>
> Hi Lin
> Unfortunately, the image frequency at the input is always twice the IF away from the signal of interest. Since the IF goes from 0Hz to 1GHz in your scheme, the image frequency will be between 0Hz and 2GHz away from the signal of interest. For example, with the LO at 2GHz, a signal at 1.999GHz will convert to an IF of 1MHz (2000 - 1999 = 1). Unfortunatly, a signal at 2.001GHz (which is out of band but might still be present on the input) will also convert to 1MHz (1999 - 2000 = -1. The - sign is irrelevant since this is just a phase change). It would not be possible to design a filter that goes on the input that passes 1999MHz but rejects 2001MHz. Your spectrum analyser with a 2GHz LO would display the 1-2GHz and 2-3GHz spectrums simultaneously, much like the current design displays 0-1GHz and 2-3GHz signals simultaneously. Of course this is only a problem if out-of-band signals might be present on the input but this is often the case.
> To avoid this issue, it is important that the IF is as high as possible since this creates a gap in which a filter on the input can roll off the response to the unwanted image frequencies. With the current MSA design with its 1.0133GHz 1st IF, filters could be placed on the input to pass 0-1GHz and reject 2-3GHz and vice-versa so that the 1G band and the 3G bands could be displayed separately if required. This is why I kept the 1st IF near to 1GHz in my scheme.

> > > > Â After some reflection, let me respond to your comments.

> > > > Your assumptions are quite correct. For sure, both 2G and 3G MSA operations are not "proper" topology, they are "icing on the cake". The cake is 1G. For "proper" topologies, to minimize spurious, it would be best to have a stand-alone MSA for each band. Adding the Mixer 0 topology will work, but has the potential to introduce another magnitude of spurious. (Plus that added cost). In my honest opinion (and how I use an analyzer, it is not worth the cost/complexity.
> > > > Â As pointed out, the 3G Band contains only a few obvious spurs (total "inop" when trying to look at an external signal at, or near 2026.6 Hz). However, I think it is a minor encumbrance when the rest of 3G is quite good. (All that icing with a small bare patch).
> > > >
> > > > Â 2G in MSA has image frequencies completely across the band. Nobody in his right mind would design a Spectrum Analyzer with this topology. (VNA operation here is not affected). The user needs to understand that if he is looking for unknown signals, he cannot be immediately assured that a response is a normal or image signal. It would be nice for the MSA to do something automatically and say "the response you see is a normal signal" or "the response you see is an image signal". Until we (Sam and I) come up with something cool, the user can manually determine this ambiguity. Here are two ways it is done:
> > > > 1. If your MSA has at least two Resolution Filters that are not the same frequency: Example, Path 1 =10.7 MHz and Path 2 = 10.11 Mhz

> > > > Date: Saturday, January 1, 2011, 4:00 PMÂ Hi EveryoneI fully understand that the original design for the MSA had a 1GHz frequency limit and that the 2G and 3G bands were added on later "for free" just by some clever changes to the software and adjustments to the circuit topology.Â As such, it is to be expected that there are some small deficiencies with the operation of these bands,Â In particular, there are images at 21.4GHz offset in the 2G band, and the 3G band has a large spur at 2026.6MHz.Â Please don't think I am being

critical in any way of the design of the MSA since I appreciate that one of the key design goals was to make the device as cheap as possible while still achieving sufficent degree of usefulness.Â It does this admirably.However, I wondered what would be needed to change the existing design so that it had "proper" 2G, 3G, and perhaps higher, bands.Â What I mean by "proper" is bands which Â have the same quality as the 1G band. ie
> > > > freedom from large spurs and images.Â Has anyone given this any thought?I am very inexperienced at RF design, but, for what it's worth, and to start off a discussion, here are my ideas (WHICH MIGHT BE UTTER RUBBISH, SO PLEASE DON'T MISTAKE ANY OF THE FOLLOWING FOR A GOOD DESIGN SUGGESTION).Â My understanding is that the basic problem with the 3G band is that the 1st IF lies within the range of required LO frequencies and so leakage through the mixer when the LO is at 1013.3MHz causes the large spur.Â In the 2G band, the problem is that the 1st IF is too low (10.7MHz) which makes it impossible to separate the frequencies of interest from their image frequencies.Â In both cases, a different 1st IF would alleviate the problem.Â A first IF which is just below 1GHz would cure both of these issues, however, the 1G band requires that the 1st IF is above 1GHz, otherwise an input signal which happens to be at the same frequency as the 1st IF would leak
> > > > through the mixer and cause noise across the whole spectrum.Â It looks, therefore, that two different 1st IFs are required to support the three bands, but since the cavity filter is tuned to the 1013.3MHz, an additional cavity filter would be necessary along with the associated swiching arrangements.Â The cavity filter is bulky, time-consuming to make and quite expensive unless you happen to have all the materials to hand and so I wanted to avoid having to include another one in the system.I wondered about the possiblilty of adding another mixer and PLO in front of MIXER 1 in the current design to create a new 1st IF (I call it IF0 from here on) that can be swicthed between a frequency just above 1GHz and just below 1GHz depending on the band.Â The exisiting MIXER 1 could then be used to convert either of the two different IF0 frequencies to 1013.3MHz as normal.Â I have attempted to show the arrangement in the attached pdf file (I hope my attachment
> > > > works!).For the 2G band, IF0 is set to 986.7MHz and the new PLO, PLO0 is swept from 1986.7MHz to 2986.7MHz.Â I appreciate that this is outside the capabilites of the current PLO and so a new design would be required.Â PLO1 (exisiting) is set to a fixed frequency of 2000MHz) which will convert IF0 to 1013.3MHz.For the 3G band, IF0 is also set to 986.7MHz with its PLO swept from 1013.3MHz to 2013.3MHz.Â This can be done by the exisiting PLO1 design.For the 1G band, two possibilities exist.Â PLO1 is not really needed for this mode since the new PLO0 could sweep from 1013.3MHz to 2013.3MHz so that the output from MIXER0 (the new mixer) could feed into the cavity filter directly.Â However, this would require some signal switching to bypass MIXER1 when the 1G mode is selected.Â An alternative would be to sweep LO0 from 1018.7MHz to 2018.7MHz, creating an IF0 of 1018.7MHz.Â If PLO1 is set to 2032MHz, MIXER1 will output the required 1013.3MHz without any

7406. SMA polarity - arghh

Yahoo group: spectrumanalyzer (2011)
Date: 2011-01-06 03:49:11 UTC
From: pzerkel
Topic: 7406 Message: 7406

As I started to prepare my SMA connectors to solder onto the ADC tonight, I realized that I have PCB SMA connectors and cable-end connectors that LOOK LIKE they would mate up. The threads mate up -- but they both have male center pins!

So I've spent the last hour reading about SMA, RP-SMA, the FCC, Wi-Fi, etc. and have seen lots of opinions.

Clearly, I need to either purchase different PCB SMA connectors (with the "old" female center pin, OR purchase coax end RP-SMA connectors with the "new" female center pin. I hope that makes sense.

So, is there any good reason to go one way or the other? FWIW, I probably have more of the SMA PCB male-pin connectors now, than I do of the male pin coax ends.

And yes, Scotty, this exercise has made me seriously reconsider the 'direct coax' connection method.

"Arghh" is right!
 I never thought there could be any confusion. All of the SMA connectors for mounting on the modules have been designated as females. If you make them males, it would be a hardship if you wanted to trade or sell modules to other builders.
  I would suggest you keep in conformance with the design.
Scotty

About a year ago, I also ended up with a batch of the reverse-polarity connectors. There was nothing in the description to indicate they were reversed, although it turned out the letters "RP" were embedded somewhere in the part number.

I thing the RP types are intended for antennas; perhaps so that you can only attach an antenna to a connector which expects to be connected to an antenna, and therefore meets FCC radiation requirements. If you use them, you will create no end of confusion for yourself in the future. I would throw them away.

Sam,

Glad to know that I am not the only one. I believe I will follow everyone's advice and not use the "RP".

I did find this page which gives a short but good description of the history of the "problem". http://www.sparkfun.com/tutorials/140

7411. Image-free 2G

Yahoo group: spectrumanalyzer (2011)
Date: 2011-01-07 17:27:30 UTC
From: Sam
Topic: 7411 Message: 7411

With the recent discussion of using a down-converting front end to bring high frequency signals into the 0-1GHz range, it occurred to me that you could view most of the 2G signals by using LO2 (1024 MHz) as the LO for the front-end mixer. In SA mode you don't need to mix LO2 and LO3 for a TG signal, so you could use that extra LO2 output for the external mixer. With filtering limitations, this would probably let you view 1074-2024 MHz by shifting it down to 50-1000 MHz. The advantage over normal 2G would be the absence of ghost images.

An alternative way to do this would be to build an extra PLO1 (or PLO3) module to use as the external front-end LO. This would give you a lot of flexibility to view signals in the 1-3 GHz range, once you had a way to control the new LO frequency. Since its frequency would be changed only occasionally, a slow communication method such as a USB-Parallel converter could be used. Or see this page for the use of a thumbwheel and a USnooBie board to control an LMX2326:

<http://www.thegleam.com/ke5fx/stellex.htm>

That extra LO could also be used as a signal generator independent of the MSA, although it would only produce frequencies at fairly large increments unless you combined it with a DDS.

To carry this a step further, the above-cited page shows how to control a YIG tuned oscillator by means of a Stellex control board (which in turn uses the LMX2326). Both the control board and the YIGs have become widely available on eBay. The control board supposedly can handle the range 2-12 GHz (subject, of course, to the limitations of the YIG range.) This would let you reach very high frequencies.

Hi, I am very surprised. I have had three follows up to my email of August 2010 two today and another a few days ago.
Just to let everyone who might be interested, the kit of bits for Scottie's Spectrum Analyzer Project, was sold very soon after advertising it on here.

Only goes to show how well thought of Scottie's design is.

To all those who are looking for a kit. I suggest that put your request that are seeking one on here. I am sure there will be others who will never get round to building their kit and would be willing to pass it onto someone who will.

Good luck in your search.

Dave,

I am having a problem with usb_configure when both the N2PK and the MSA are connected. Basically, with usb -configure I can configure and work with either one but, again, not both at the same time. In the setup tab, selecting the confihguration string does not necessarily result in finding the device. It appears that Windows 7 only recognizes one or the other driver but not both.

7414. Spectrum analyzer kits available anywhere?

Yahoo group: spectrumanalyzer (2011)
Date: 2011-01-09 11:35:39 UTC
From: vk2ben
Topic: 7414 Message: 7414

Hi everyone,

Back in August last year, one of our fellow members advertised that he had a full kit of boards and bits required to build up one of Scottie's MSA's.

Unfortunately (for me and a couple of other "kit hunters"), that gear was snapped up very quickly.

This has prompted me to ask the Group: has anyone else out there collected a complete, or mostly complete, kit of parts that either just needs constructing or perhaps needs a few more parts added to get it going?

Please let me know. Depending on what sort of investment it will require (it seems the cost of building an MSA can vary wildly), I may put my hand up to relieve you of it ;-) If it is out of my reach for the moment, perhaps somebody else in the Group would like to make an offer to you.

Anyone have a kit collecting dust out there?

I look forward to hearing from any takers.

Cheers,
Ben

Hi group,

I've considered offering a kit of parts and boards, again. It would be helpful to determine the level of interest. Please contact me off-list to express your level of interest in boards, small kits or a master kit of parts.

7416. USB Questions

Yahoo group: spectrumanalyzer (2011)
Date: 2011-01-09 17:29:51 UTC
From: nealmartini
Topic: 7416 Message: 7416

Sam, David, & Others USB Knowledgeables,

I am trying to understand the documentation I find in the group files w.r.t. USB an dthe MSA. I am not very well versed in USB, so I apologize if some of my questions are naive. Here are a few questions I have:

1. Does the latest MSA software release have full support for USB, including the .dll and menu select options? Or is there a special version of the software for USB support?

2. If the answer to number 1. is yes, does the included driver assume the pin assignments shown in the files document for connecting a CY68013A USB controller board to an existing MSA Control Board?

3. If you connect a CY68013A USB controller board to an existing Control Board, is there any throughput hit?

4. I assume it is WIN7 compatible.

5. Is someone designing a SLIM version of a USB board that can be used in place of the current MSA Control Board.

Sorry for all the questions. Thanks in advance for your help on this.

Neal

Neal,
The next release of the software, for which the beta has been posted, will provide full USB support by making calls to Dave's driver. You would use the Configuration Manager to tell the MSA software that you are using USB rather than the parallel port. I'll let Dave respond as to the details of the driver.

The general plan is to be able to allow users to control the MSA through the existing control board or directly, bypassing the control board. My plan is to wire an off-the-shelf Cypress board ($30) to the parallel port input of the control board. I suppose in theory it is slower to run the data through the existing control board, but I doubt there would be a measurable speed hit. USB likely will be faster than the parallel port, so the dominant factor in determining overall speed will be the processing of data, not communication with the hardware. In VNA modes, the dominant timing factor will generally be the amount of wait time needed to allow full settling.

I don't know of anyone designing a direct control board replacement that would contain the Cypress chip. For anyone who directly wires a Cypress board to the modules, I did design a board that provides +10V and +23V supplies--a similar concept to the Control Board but without the latches. That board was included with the Signal Router board for which there was a recent group buy.

It might be feasible for someone to merge the layout of the +10/+23V board with a Cypress board layout such as Dave Brainerd's.

Hi Neal,
This is my take on the subject:
- I have been running Windows 7 64 bit
- Release 116, as released a couple of days ago, supports USB. Not all the functionality is still available, for example, only the resolution filters are selectable. There is only one version of the software both usable with USB or the control board.
- The pin assignments to the CB are correct. I run USB like that up to a couple of days ago. I am in the process of moving everything to a new box that will not use the CB: only USB. I HAVE CONFIGURED USB ALREADY AND THE SOFTWARE IS TALKING TO THE HARDWARE. AS WE SPEAK, I AM STILL TESTING.
- I have had issues with the installation USB drivers that Dave is helping me with.

I hope the above is of some help.

7419. video filter

Yahoo group: spectrumanalyzer (2011)
Date: 2011-01-10 16:51:00 UTC
From: Sam
Topic: 7419 Message: 7419

I am finally testing my automated video filter, which is now crudely installed in my MSA. Its basic functioning is fine; my main concern was whether the 100 ohm series resistors on the large capacitors will unduly limit the filtering action. They are there to reduce the discharge surge when the power goes off. They do cause some reduction in filter efficacy, which caused me to make a couple of changes. On the Mag filters, there are two large capacitors, 10 uF ("Narrow") and 100 uF ("XNarrow"). I reduced their series resistors to 47 ohms. I also added a shunt 1 uF capacitor in parallel with the 100 uF/47 ohm combination to provide some filtering that is free of the resistance. The results are very good so far. I am also considering increasing the 0.1 uF capacitor (the "mid" filter) to 0.33 uF to give it a bit more oomph.

In the beta software, you can list your capacitors in the Configuration Manager, so you can use whatever values you are happy with.

I'd be interested in feedback from anyone else who has tried tinkering with the automated video filter.

Sam, can you or anyone else identify a tinylogic sized chip with only 3 legs (2 on one long side and one on the other) that is marked "TOAG"? I'm sure I bought them for something associated with the SA, but the term also has some meaning associated with an Egyptian god of some sort and Google is no help at all. Maybe a regulator???

7422. 116 beta

Yahoo group: spectrumanalyzer (2011)
Date: 2011-01-10 21:03:42 UTC
From: Sam
Topic: 7422 Message: 7422

I posted a new version of the beta version 116 software in the Files section at:

<http://groups.yahoo.com/group/spectrumanalyzer/files/MSA_version116_4d_Beta.zip>

This fixes a couple of irritating bugs--one with saving files and one with the Filter Analysis function. It also contains a new test routine created by Scotty for scanning/tuning the cavity filter without having to tinker with cables, which isn't documented yet but will be when any kinks are ironed out.

Sam W.

I took a couple of guesses and looked up the parts, but they didn't work. I have used a couple voltage references and a 2907 transistor in that type of package, but their markings don't fit. Scotty used a pre-biased transistor in SOT-23; I don't recall the exact number(MUN...) but the one I guessed at had the wrong markings. That's all I can think of.

7424. Resolution filter shape

Yahoo group: spectrumanalyzer (2011)
Date: 2011-01-10 23:06:54 UTC
From: Mark Burgin
Topic: 7420 Message: 7424

Hi Everyone
At the moment, I only have a single completed resolution filter with a 7.5KHz nominal bandwidth. It uses the ITT 024DD MCF from eBay which seems to have the same specs as the QMF 10725 described on Scotty's web site.
My problem is with the shape of the filter's response. Its bandwidth (7.9KHz) and insertion loss (about 3dB) are both OK, but my problem is that it has a fair amount of passband ripple. I measure it as about 1.3dB even after tweaking the matching with variable caps. Now this wouldn't be so bad if the maximum of its reponse was in the centre but, unfortunately, there is a bit of a dip in its reponse near to the centre so that its maximum is significantly to the right of centre.
How should I calibrate this path? Using the maximum value or the value in the centre of the filter's reponse? Are there any tricks I can try to get the maximum more nearly in the centre?
As a side question, what is the ideal resolution filter shape? Should it be flat-topped with cliff-like sides or more rounded in its shape? On the one hand I imagine that flat-topped is best since this introduces least error if a narrow bandwidth signal if within the passband of the filter but not exactly at the centre, but the more rounded shape helps to ensure that maximum reponse occurs near to the filter's centre frequency so that I get more precise measurements of the frequencies in the signal.
Thanks
Mark

Hi Mark and all,

I have the same problem with the same filter. I just assumed that I had the wrong value Z matching components on the input and output. I have made no
attempt to tune it yet. I just threw it together to get something that works. I have some matched crystal sets that I will eventually make 4 resolution bandpass filters with.
But I have the same questions about ideal passband response.

If we look at the commercial SA RBW filter shape, it is similar to a triangle.
http://groups.yahoo.com/group/spectrumanalyzer/photos/album/608125393/pic/1237712515/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc
It is not top flat.

Hi Mark,
The perfect filter would peak in the center and look somewhat elliptical within the 3 dB points. Also, the skirts would be very sharp. Almost impossible to have both with one filter.
 Anyway, to answer your main question, calibrate for the exact center of the filter, even if a "dip" is there.
Scotty

Hi EveryoneAt the moment, I only have a single completed resolution filter with a 7.5KHz nominal bandwidth. It uses the ITT 024DD MCF from eBay which seems to have the same specs as the QMF 10725 described on Scotty's web site.My problem is with the shape of the filter's response. Its bandwidth (7.9KHz) and insertion loss (about 3dB) are both OK, but my problem is that it has a fair amount of passband ripple. I measure it as about 1.3dB even after tweaking the matching with variable caps. Now this wouldn't be so bad if the maximum of its reponse was in the centre but, unfortunately, there is a bit of a dip in its reponse near to the centre so that its maximum is significantly to the right of centre.How should I calibrate this path? Using the maximum value or the value in the centre of the filter's reponse? Are there any tricks I can try to get the maximum more nearly in the centre?As a side question, what is the ideal resolution filter
shape? Should it be flat-topped with cliff-like sides or more rounded in its shape? On the one hand I imagine that flat-topped is best since this introduces least error if a narrow bandwidth signal if within the passband of the filter but not exactly at the centre, but the more rounded shape helps to ensure that maximum reponse occurs near to the filter's centre frequency so that I get more precise measurements of the frequencies in the signal.ThanksMark

As well as tweaking the caps on the matching network, I'll assume that you are using a L network, you could try adjusting the L. Difficult if you are using SMD chips but I am using some FT23-61 cores so it is easy to wind a couple of turns more than the computer prog suggests and then remove one at a time until the best match is found. I use the program mini Ring core Calculator from DL5SWB to calculate the turns initially.
Also, the Z on each side of the filter will be different and neither will be 50 ohms.

Topic: 7429 Message: 7429

Just over a year ago, many of us took advantage of the very generous offer to obtain the sets of crystals to build the resolution filters.
Scotty followed this up with a note describing the nature of the crystals together with a warning concerning the fragility of the leads. These leads are very delicate and WILL break if you try to bend them more than once. Just very carefully straighten them and then solder them onto the board. Believe me, I broke two leads on my first attempt but managed to solder through the plated through holes to rescue the filter.

The excellent program Dishal 203 will guide you through the design stage but assumes that all crystals are the exactly same so be prepared to experiment with values. I used at least two caps for each value, one at about 75-80% of the target value and the other selected on test. To make it easier to change the caps, I solder two short pieces of wire (scraps from wire ended resistors) at each location and solder the C's to these until I get the best result. Then remove the wires and solder the SAME C's in their final place. You have in effect eleven C's and two L's to play with so be prepared to spend some time to get it right. The computer program will give you the filter impedance but do not assume that the circuits connected to the filter are 50 ohm, they will be close but will require tweaking to get the response correct.
I found that the maximum bandwidth that Dishal designs for is about 7kHz so I am going to have to resort to commercial units to get the wider bandwidths. I haven't built the very narrow filter yet but I am aiming for about 500Hz. If anyone knows if greater bandwidths can be obtained using the sets supplied, please pass on how it can be done.

Good luck

Geoff

I posted a reply this morning, but it seems to be lost in the ether.

A possible cause of the dip in the response is under-transformed impedance. For example, if you are trying to match 50 to 2500 ohms, maybe your components are matching 50 to 2000 ohms. This can easily happen even with correct L and C values, if the inductor is low Q. I built two filters with this same MCF and got good results. See my photo album (SamW--RBW Filters).

I wound the inductors on small binocular cores (BN-61-2402) and measured them with the AADE meter. If you already have the MSA up and running with one RBW filter, you can use the MSA itself to measure the inductors (simplest method is to use Component Measure function). Let's say you need more than 3 but less than 3.5 turns. Glue a second core to the first, put 3 turns on the first and try 1-3 half turns on the second. This gives you more fine-tuning than a single core. (A half turn on an empty core gives much less inductance than a half turn on one that already has 3 turns.)

From: Sam
Topic: 7429 Message: 7431

As you say, the Dishal design is great below about 7 kHz but not so good above that. The good news is that you can build a very simple 61 kHz bandwidth filter by cascading two ceramic filters, as shown here:

<http://groups.yahoo.com/group/spectrumanalyzer/photos/album/271352628/pic/471013266/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc.>

That image was taken using resistive impedance matching to 330 ohms, but of course you would want to use LC matching. If you had filters of 500 Hz, 7.5 kHz, 61 kHz, and something in the area of 300-1000 kHz, you would have a nice filter selection. Something in the 300-500 kHz range could also be simply done with ceramics, as shown in the same photo album.

You can to some extent take into account the individual crystal characteristics in the Dishal design. It has been a while since I played with it, but there is even a way to adjust for off-frequency crystals, but I could only figure out how to do it for the first and last crystals in the ladder. Once you have the basic design, you can simulate it in RFSim99 using the actual characteristics of the individual crystals, and tweak capacitor values as desired.

Creating the RFSim file is a bit of a pain, because it only allows limited precision, so you have to create two series inductors for each Lm and two parallel capacitors for each Cm, and use one of them to set the final decimal positions. I created such a file, which I thought I posted, but in fact I posted only a graphic image of the simulation results. That was in XtalFilt2.zip in the Files section. I have now added the actual .cct file (the RFSim99 format) to that zip file.

Even with all of that, your actual capacitors won't match the theoretical values, so you need some tuning ability. You could do that with tiny variable caps; when you are done you could remove and measure them, and replace them with fixed caps.

Dear all,

If anyone need BLF369 I have several pieces.

I don't have time to experiment on them anymore and i'd like to sell them
@$250pcs each (negotiable)

Date code : 0724

Brand : NXP

Condition : New.

Payment via Paypall.

If anyone interested please contact me directly via email.

Regards,

Dwi Hartanto

Thanks for the suggestions, everyone.
I had a look at the video, Jerry, and it is quite a dramatic improvement (incidently, the link didn't work for me but I found it on YouTube anyway).
I have already tried to match the filter's input and output as well as I can. I ended up with a 3uH inductor and shunt 68pF plus 4-25pF variable caps. I found that I could minimize the ripple at a point within the adjustment range of the variable capacitors, but could never get rid of the dip near the centre of the response. I haven't tried to vary the inductors since these are just fixed value SMDs. Since I have "tuned" the response using the caps, is it necessary to be able to adjust the inductors as well? I guess that only when both the capacitors and inductors are correct will they resonate at the right frequency and produce the right impedence transformation. But would it make a noticeable difference if I altered the Ls as well?

I forget the matching impedance for that filter, but let's say it is 2500 ohms with shunt 10 pF. If you match with a series L leading to the filter, and then a shunt C, think of it this way: A certain LC combination will create a resistive transform, which ideally would be 50:1 (or 1:50, depending which end you are looking at). You then increase the C value by 10 pF to create the net shunt capacitance. Adjusting C adjusts the net capacitance, but not the underlying resistive transform. If your transform is really 40:1, no amount of adjusting C will change it to 50:1. You have to adjust L to do that.

Even so, it is normally possible to get an accurate enough value of L that you don't need an L adjustment. However, that is difficult if you use SMT inductors to make large impedance transforms. SMT inductors may be 10-15% off the target value (partly due to tolerance, partly due to the fact you normally can't get an off-the shelf inductor with exactly the nominal inductance you want). In addition, SMT inductors generally have Q in the 15-30 range, which can have a dramatic effect when you are making large transformations.

In RFSim99 you can generate the LC components for an impedance match and then change the inductor Q to see what effect it has. When matching 50 ohms to 330 ohms, the Q value is not too critical. When matching 50 ohms to 2500 ohms, a Q of 15 has a dramatic effect and even a Q of 30 has a significant effect. One of the results is that the effective transform may become 50:2000 rather than 50:2500. To compensate for that requires a larger L. Or, use a handmade inductor to get higher Q.

To get an accurate handmade inductor, you can measure the inductance with the MSA. Even though your current RBW filter is not ideal, it should still do a fine job in VNA modes, so you should get accurate component measurement. So you could use this filter to create the necessary inductors to improve this filter. Seems like that should violate some law of physics.

For a simpler approach, you might just try the next larger size inductor, and see what effect that has. (You should change the inductors on both sides of the filter.) Or, if you have room, add a series inductance of 300 nH or so.

That's a nifty video. I wouldn't mind doing a few of those for the MSA, if I can find the software. There is Windows Media Encoder, but it requires at least XP and it would be more convenient for me to use my computer with 2000. (My XP computer is in my workshop. I have to stand up to use it and the keyboard access is awkward.) Does anyone know of software that would essentially do a continuous screen capture so as to make a movie out of what is occurring on the screen, and would work on Windows 2000?

From: Robert Fish
Topic: 237 Message: 7440

Hi Guys,

I am trying to test my newly built control board with the controltest.bas software. It failed and i just remembered why. I had to add an after market I/O card to my new computer to get a parallel port (my computer didn't come with one).
It just occurred to me that I have to tell this new software where to find my parallel port. To make the MSA software work on my computer, the address that I have to put in the Harware Configuration manager is "HEX B900" (without the quotes).

In controltest.bas there are three lines at the beginning of the code:

```
port = hexdec("&H378") 'printer port data address for specific computer
status = hexdec("&H379") 'printer port status address for specific computer
control = hexdec("&H37A") 'printer port command address for specific
computer
```

It is clear to me that somewhere inside the parenthesis I need to add HEX B900. Do I add the same address to all three lines Port, Status and Control (because they are different in the default code).
What do I replace in each set of parenthesis? Everything except the Quotes?

I am not a software guy obviously.

Thanks,

Bob

From: D. J. Wang
Topic: 237 Message: 7441

I would try this:

port = hexdec("&B900") 'printer port data address for specific computer
status = hexdec("&B901") 'printer port status address for specific computer
control = hexdec("&B902") 'printer port command address for specific

Port, status and control use different addresses..

Subject: [spectrumanalyzer] Printer Port

Hi Guys,

I am trying to test my newly built control board with the controltest.bas software. It failed and i just remembered why. I had to add an after market I/O card to my new computer to get a parallel port (my computer didn't come with one).
It just occurred to me that I have to tell this new software where to find my parallel port. To make the MSA software work on my computer, the address that I have to put in the Harware Configuration manager is "HEX B900" (without the quotes).

In controltest.bas there are three lines at the beginning of the code:

port = hexdec("&H378") 'printer port data address for specific computer
status = hexdec("&H379") 'printer port status address for specific computer
control = hexdec("&H37A") 'printer port command address for specific computer

It is clear to me that somewhere inside the parenthesis I need to add HEX B900. Do I add the same address to all three lines Port, Status and Control (because they are different in the default code).
What do I replace in each set of parenthesis? Everything except the Quotes?

I am not a software guy obviously.

Thanks,

Bob

That should work. I might also add that the beta software contains a built-in control board tester (Setup->Special Tests->LPT Port Test) that allows testing individual bits and also allows you to specify the port's base address (B900 in this case). That software is in the Files section (MSA_Version116...).

This tester controls the state of the parallel port lines. To change a latch bit, you need to change the appropriate data line (D0-D7) and then set to one the line that controls the latch enable signals; those lines are labeled Sel (Latch 1), Init (Latch 2), Auto (Latch 3) and Strobe(Latch 4). Or you can just leave the latch enable lines high while you mess with D0-D7.

When changing individual bits, beware of shorting two adjacent bits with your probe, because a high output shorted to a low output can burn out a bit.

Sam W.

It's a long time since I did these tests but to prevent any mishaps, I made up a very simple "tool" consisting of a spare connector fitted with LED's with current limit resistors to be plugged into each connector, P1 to P4, in turn.
This enabled the status on all 8 lines to be monitored at the same time. The tester has since been dismantled and the LED's etc returned to "stores" box.

Hi Guys,

The other day I was putting together a parts order for the two DDS SLIM's so the parts will be here when I get to those modules.
When I tried to order the AD9850 chips, Digikey said they were on backorder and there would be a wait. It wasn't terrible, I think it was 3 weeks or something. Just for kicks, I jumped over to EBAY to see if there was anybody selling them there. There were several folks selling 9850's there and the price was about 20 or 25 bucks, same ballpark as Digikey. Then I noticed one seller selling them for $5.99. At first, I thought it was an auction that hadn't ended yet. But no, that is the asking price. The guy states that it might take a month for delivery.
He is in China. I said, "what the heck" and ordered two of them. This was a week ago. They arrived today, brand new cut off of a tape and reel or whatever you call it.
What do you guys think ? Is there a such thing as bootleg chips? I wonder if they work.

Here is the link:

http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=140493448505&ssPageName=STRK:MEWNX:IT

I'm going to give them a shot and see if they work. They either work or they don't, right? or can they under perform, noisy maybe?

Sorry for the long post,

Bob

I've gotten some bargains like this on Analog Devices chips
before, but some were obviously obtained by someone through
a free sample program and resold. They seem to work fine, but
the ethics of doing that are a little suspect.

From the wording of how long it takes to "prepare" the chips,
it almost sounds like they are pulling them off scrap boards and
then sending them out, but if they look like cut tape, I guess that's
not the case. Sparkfun got burned on some bogus Atmel chips
recently, so yes there are bootlegs:

Hi Bob,
I bought 5 AD9850 from a Taiwanese vendor on eBay few month ago, it is probably the same guy. I think he is still selling them at 5 for $18.99 plus $3 shipping.

I bought 5 for a similar price about a year ago. They were listed as "used" but I doubt they were. They looked clean and were mounted in tape. I have used them in my MSA. One drew about double the supply current so I changed it (10 ohm to 78M05 getting warm). Still have two spare. My MSA is working fine.

As Scott wrote,

buying two's might be buying "free samples". I don't think AD have any "free" AD9850's anymore as they don't like us doing new designs with them. They are kindof obsolete or at least going towards EOL (and unethical...)

However!

Samples are often lacking the final production stage of "tempering".

They must be baked for 24 ours in125 degrees centigrades.

AD's wording: "Failure to comply may result in crack nd/or delamination of critical interfaces within the package. Reference IPC/JEDEC J-STD-033 for additional information."

Treat your chips as "samples", just in case, and bake them accordingly before you solder them.

Cheers

Sam,
It appears that the software calls msadll.dll even when the USB interface is not selected in the hardware setup. If running with the parallel interface with msadll.dll present in the directory AND the USB interface not plugged in, this results in an error message. If msadll.dll is not present in the directory (or is renamed) then everything is OK. Not too serious unless msadll is read regardless it is needed or not.

BTW, are you running USB with the control; board or do you go directly to the SLIMs ? I tried to go to the SLIMs directly and couldn't get it to work, I am going back temporarily to parallel; I may have messed the hardware..

From: wsprowls
Topic: 7454 Message: 7454

Hi All,
For those of you who are trying out the Version 116 Beta software, there are a couple of new features in the Special Tests Window.
1. Testing the LPT Port on the Computer. This will replace the old LPT code I have been passing around. Much simpler to use. Here is a page on how to use it:
http://www.scottyspectrumanalyzer.com/special_lpt.html

2. Testing the Cavity Filter without having to disconnect any cables. Really nice (if I do say so myself). Here is the description page:
http://www.scottyspectrumanalyzer.com/special_cavitytest.html

Cheers,
Scotty

Hi

I've been using the new cavity filter tuner and it's great. A very clever use of soft and hardware!
However I noticed one flaw, maybe it's me, but the filter analysis function crashes the program. I've tried the "B" version but is has the same problem. Something to do with a #handle 'color' ?

Regards,

Simon

Hi All,
For those of you who are trying out the Version 116 Beta software, there are a couple of new features in the Special Tests Window.
1. Testing the LPT Port on the Computer. This will replace the old LPT code I have been passing around. Much simpler to use. Here is a page on how to use it:
http://www.scottyspectrumanalyzer.com/special_lpt.html

2. Testing the Cavity Filter without having to disconnect any cables. Really nice (if I do say so myself). Here is the description page:
http://www.scottyspectrumanalyzer.com/special_cavitytest.html

Cheers,
Scotty

Adding the .g to #handle is correct. I thought I had fixed that. Strange. In your text, the reference to graphBox$ should be gBox$, which is how the code reads.

I will have to leave that for Dave Roberts to resolve. I don't actually use USB at the moment and I have steered clear of the details of the USB interface. (I'm all in favor of USB, I just have plenty of other things to deal with.) Some of the initial DLL accesses occur before the configuration file is loaded, so maybe the problem is there.

You're right, in attempt to find the bug I renamed gbox into graphbox and forgot to put it back. I don't know anything about Basic just Assembler so I had to try things....

Sam,
1. The Auto-wait checkbox is not available in this version. Also the capacitor values that show on page 3 of the summary changes don't correspond with the schematic.
2. Question: are the video filter capacitor values which are entered in the Hardware Configuration setup table actually used by the program? If that is the case these should be measured values not just the nominals.

Jim
The auto-wait checkbox shows up on mine, and works when I click it. Could you send me a screenshot of your sweep parameters window?

Yes, the schematic values for the video filter were adjusted after the software default values were set. I think I got the default values from Scotty, but I tinkered with them. Everyone should enter the values they actually use. If you are more interested in rapid SA sweeps, you may want to go with smaller capacitors. I'm more interested in smoothing VNA sweeps, so I go with larger capacitors. The software makes use of the capacitor values, but it is not necessary to know their precise values.

Auto-wait watches the readings settle, and decides when the remaining amount of possible settling is too small to bother with, based on the time constants of the capacitors. There is an error factor because the actual wait time between readings is almost always longer than the software thinks, so the amount of settling that occurs in that time interval is greater than it would be if the wait time were more precisely known. This tends to make the software project more future settling than will really occur, so it will frequently wait one time constant longer than it really needs to. So it is being conservative. In this context, a 20% error in the capacitor value is unlikely to cause any harm. On the other hand, if you can easily measure your capacitors, you might as well do so.

Note also that there is some small capacitance in the circuits (e.g. on the PDM board) even if you use no Wide video filter capacitor. The default values of the Wide filter reflect those capacitances (e.g. 0.011 for phase). But the defaults assume 0.1 uF for the Mid filter, and enter it as 0.1 rather than, say, 0.111 for phase (which would include those other capacitors). The difference is not meaningful enough to bother with, and gets confusing. But you can certainly add that extra capacitance to your measured capacitance if you want to be more precise.

So "close" counts in horseshoes, hand-grenades and configuring the capacitor values.

Jim,
This probably has to do with the irritating message you mentioned earlier about the cal table being too sparse to use auto wait. I eliminated the message, but auto wait is disabled in that situation. You are probably running with the default path calibration, or an actual calibration that has very few points (auto wait requires at least 5 cal points, as I recall). Auto wait has to adjust to the fact that the bottom, center and top portions of the ADC vs. dBm curve normally have significantly different slopes, so it checks out those areas when a path cal is loaded. You could either do a more full calibration, or just add a few points by rough interpolation or extrapolation.

There are also a few other situations where the software cannot calculate the necessary information if the path cal data is screwy, but those situations should never arise with real calibration data.

Hi Sam,
I see your reasoning. I just populated path 1 and I get the AutoWait. BUT it also shows if I switch to P2 and P3 which are not populated.

On another vein: both ADC outputs are always active, I see signals going out for both mag and phase. When the systems wakes up as SA, the Show Variables panel, however, does not show any phase activity. If now I change mode to VNA, I can see phase activity. So far OK. But then, if I return to SA, the pase activity continues. I don't think this is causing any problem other than unnecessary processing while in SA mode.

Just being picky....

7465. Auto Wait

Yahoo group: spectrumanalyzer (2011)
Date: 2011-01-16 23:18:16 UTC
From: Sam
Topic: 7013 Message: 7465

Jim
At this moment, Yahoo seems to be in la-la land. My prior message has not yet been posted and it won't let me "reply" to messages. But I assume that message and this will ultimately get through.

Regarding the fact that the auto wait box still appears with your sparse P2 and P3 calibrations. If auto wait is already selected when a new path is loaded, the disabling of auto wait for sparse calibrations doesn't work. I have now fixed that.

Sam W.

Jim,
When in SA Mode, the Phase bits are read at the same time the Mag bits are read, but not processed. Therefore, no wasted time.
Exception: When in SA Mode and Variables Window is open. Then Phase bits get displayed in the Variables Window but no other processing.
 This was my idea to verify that the Phase bits were working during testing. I left it there for a possible use of the Phase AtoD for applications with the SA without VNA.
Example: a digital voltmeter.
Scotty

Jim,
This probably has to do with the irritating message you mentioned earlier about the cal table being too sparse to use auto wait. I eliminated the message, but auto wait is disabled in that situation. You are probably running with the default path calibration, or an actual calibration that has very few points (auto wait requires at least 5 cal points, as I recall). Auto wait has to adjust to the fact that the bottom, center and top portions of the ADC vs. dBm curve normally have significantly different slopes, so it checks out those areas when a path cal is loaded. You could either do a more full calibration, or just add a few points by rough interpolation or extrapolation.

There are also a few other situations where the software cannot calculate the necessary information if the path cal data is screwy, but those situations should never arise with real calibration data.

7467. Cavity bandwith vs RBW filter frequency

Yahoo group: spectrumanalyzer (2011)
Date: 2011-01-17 03:23:25 UTC
From: Jim Hontoria
Topic: 7467 Message: 7467

I just built a 1 KHz ladder filter using the 10.11 crystals..If the cavity filter has 2 MHz bandwidth and a center frequency of 1013.3 MHz this allows for an IF of 1024 -1013.3 plus minus 1 MHz.or a margin of 9.7 MHz to 11.7 MHz. This means that my new filter at 10.11 fits right in there and everything should be hunky-dory. Is this the right analysis?

Jim

Exactly. The cavity filter attenuation will be a little higher out near the edge, but that is no big deal.

When I revised the read procedure for Auto Wait, I didn't save the phase readings when in SA mode. (I have now fixed that so it behaves per Scotty's post--phase ADC is saved and displayed in Show Variables, but not used for anything else in VNA mode.) The phase activity Jim saw in the Show Variables window was the display of the phase info left over from the most recent VNA scan, which explains why there was no such activity when he started in SA mode--there was no leftover VNA phase data.

I eliminated the message, but auto wait is disabled in that situation. You are probably running with the default path calibration, or an actual calibration that has very few points (auto wait requires at least 5 cal points, as I recall). Auto wait has to adjust to the fact that the bottom, center and top portions of the ADC vs. dBm curve normally have significantly different slopes, so it checks out those areas when a path cal is loaded. You could either do a more full calibration, or just add a few points by rough interpolation or extrapolation.
>
>
> There are also a few other situations where the software cannot calculate the necessary information if the path cal data is screwy, but those situations should never arise with real calibration data.

From: Robert Fish
Topic: 7013 Message: 7470

Seems like Yahoo has been having its problems lately. One morning last week, I sent a message that didn't get posted. So I sent a second message. Later that afternoon only the second message got posted.

Bob

7471. Problems with parallel interface

Yahoo group: spectrumanalyzer (2011)
Date: 2011-01-19 20:06:21 UTC
From: Jurgen
Topic: 7467 Message: 7471

I am trying to test the A/D converters by connecting them to the
parallel interface using the PC display.
The software is installed and working as far as I can make out.
Four interface connections to the A/D converters are made.

I have data signals on U3 pins D3 to D7 but no Auto LE signal on pin 11
of U3 or pin 14 of the LPT connector.
Any suggestions on how to fix this.

Jurgen

Topic: 7467 Message: 7472

Hi Jurgen,
 Remove your parallel port cable from the computer and test those signals directly on the computer. If there, the cable would be suspect.

7473. Resolution filters (Final Crystal Filters)

Yahoo group: spectrumanalyzer (2011)
Date: 2011-01-20 05:18:29 UTC
From: wayne.salzwedel
Topic: 7473 Message: 7473

OK, I need some help! I am not sure what to use for my first Resolution filter? I understand that once I have my MSA up and running that I will be able to test filters and build some good ones for the rest of the BW steps, but what about the first one?

I have spent 3-4 days now looking for parts and I have some ideas, but no clear direction on which way to go. I don't have much for test equipment either. Does anyone have a design that will work that I can get all the parts for? I do have one of the PWB-MCF rev A boards, but have not found anything to put on it.

I am more than willing to pay for what I need, but just need some direction.

Thanks All !!

Wayne

7474. Re: Resolution filters (Final Crystal Filters)

Yahoo group: spectrumanalyzer (2011)

From: Sam
Topic: 7473 Message: 7474

If you just want a filter that can let you determine whether everything else is basically functional, you can build a 60 kHz bandwidth filter very simply, by cascading two ceramic filters and adding impedance matching components. The results are shown here:

<http://groups.yahoo.com/group/spectrumanalyzer/photos/album/271352628/pic/471013266/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc>

That image used resistors to match, but you would want to use 1.8 uH inductors (Q of at least 20) leading to the filters and 100 pF shunt to ground at the filter terminals. You likely could get by without any fine tuning, though you would probably want to tune it later.

The wide filter limits the resolution of your scans, but there is very little chance that its shape will come out totally wacko, so it at least lets you see whether the rest of the MSA works. And when you have a full set of RBW filters, this can be one of them.

For narrower filters, a simple way to get started is to buy a canned filter on eBay, such as this one:

<http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=150546045545&ssPageName=STRK:MEWAX:IT>

eBay filters don't always specify the terminating impedance, but this one does. The termination is specified as 2000 ohms,which you would match to 50 ohms with 4.7 uH inductors leading to the filter terminals and 47 pF capacitance shunt to ground from the terminals. To allow some tuning, use 33 pF capacitors and a small trimmer that goes to 25 pF or so. You don't need any equipment to tune it other than the MSA. Just install it as the RBW filter, and do a sweep with center=0 and span=0.02 MHz and you should get a nice graph of the top 50 dB or so of its response, which is all you need for tuning. Adjust the trimmers until the top of the response looks good.

For a PCB, you can use a blank double-sided board. Drill holes for the terminals and for a few ground vias. Mount the filter on the bottom and solder its case to ground. Put the components on the top with a fence running across the middle of the filter to isolate the input and output. Solder a fence around the outside of the board and solder a lid on it to cover the components. (If the fence is soldered to both the top and bottom ground planes, you can skip the ground vias described above.) It is not critical to solder the lid to the isolation fence in the middle of the filter. Poke/drill/cut two holes in the lid so you can tune the trimmers. You can cover the holes later with copper tape (or tack on a piece of brass), though it doesn't seem to cause any harm to leave them open.

I forgot the SMA connectors. Poke holes in the enclosing fence and solder the connectors to the fence with the center pin poking through the hole. A filter built with a similar approach is shown here:

<http://groups.yahoo.com/group/spectrumanalyzer/photos/album/271352628/pic/664919547/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc>

I mounted a male DB25 connector on the interface board. That seems to
incorrect, pin 14 is grounded.
Looks like it needs a female connector.

CONFUSED, how did I get there?

Can you please confirm.
There is a signal on Pin 14 but it gets shorted.

Thanks Scotty, changed the connector signals are present now.
I connected both Mag and Phase A/D inputs in parallel for testing.
SDO of the phase AD looks fine, the graph moves up/down following the
input voltage. The Mag AD only generates a single bit, it does not
change with a changing input voltage, the line on the graph is stuck at
0 dBm. Looks like a damaged AD.

Jurgen,
I had lots of trouble with that chip because of its size. At the end it was
a solder problem. I have found that if I don't clean the board thoroughly
prior to soldering problems will pop up. Now, even with a thorough clean up
I first deposit solder on the lands/ pads, remove excess solder with a wick
and then I solder the chips.

Hi Jurgen,
It does sound like the Mag AtoD input pin is shorted to 5 volts. This has happened before.
If so, remove the short. It would not harm the ic.
Read the "Hard Failure" procedure on the web page:
http://scottyspectrumanalyzer.com/trouble.html

I am trying to test
the A/D converters by
connecting them to the

parallel interface
using the PC display.

The software is
installed and working
as far as I can make
out.

Four interface
connections to the A/D
converters are made.

I have data signals on
U3 pins D3 to D7 but

no Auto LE signal on
pin 11

of U3 or pin 14 of the
LPT connector.

Any suggestions on how
to fix this.

Jurgen

7481. Relay Switching

Yahoo group: spectrumanalyzer (2011)
Date: 2011-01-22 00:46:13 UTC
From: Sam
Topic: 7481 Message: 7481

After building some switches with latched Tyco relays, I have explored some other possibilities. These relays have roughly 100 dB isolation at low frequencies (<50 MHz or so), so a single relay can be useful for some purposes. The 12 V non-latching version actually only needs 9V, and uses only about 10 mA. So I decided to try it.

Several places sell the 12V non-latching version, but all have it on backorder. Farnell and RS-Online have only about 1 week delays, but when I tried ordering the relay, neither would allow me to enter a non-UK address. Apparently they don't sell outside the UK. Does anyone know anything about those outfits?

I did place an order at Future Electronics, which is also on backorder, but they don't give me an estimated availability date. We'll see how that goes.

Assuming I can buy these things, here is my plan. I want to build a test set that includes a bridge, a buffer amp and a transmission/reflection switch. I'm aiming at relatively low frequencies on this one, both to simplify the switching and to have a frequency range where high accuracy can be achieved with minimal calibration. The DUT input would be connected to the Active Bridge, and the DUT output would be connected to the buffer amp. Up to 100 MHz, the DUT would see extremely good 50-ohm source and load impedances, and the bridge would perform very well with reference calibration. (I.e., just establish the base signal level with an Open calibration, without needing full OSL). The MSA could switch between Transmission and Reflection without cable changes and without distorting the measurements.

This board would actually be quite usable for measuring transmission and reflection with a spectrum analyzer+tracking generator, without VNA features, up to 100 MHz.

Above 100 MHz, performance would gradually deteriorate but could be corrected by more full calibration, with an ultimate limit of 300 MHz or so.

The switching would be done with a single relay. If the bridge reflection output is, say, -25 dBm (for 0 dB return loss) to -65 dBm (for 40 dB return loss), and the transmission signal is -5 dBm to -105 dBm, and the relay isolation is 95 dB, here is the situation regarding the transmission and reflection signals interfering with each other. A strong -5 dBm transmission signal could add -105 dBm contamination to the weakest (-65 dBm) reflection signal. That creates minimal error. A strong -25 dBm reflection signal could add -120 dBm contamination to the weakest (-105 dBm) transmission signal. That might affect the transmission reading by 1 or 2 dB, but that sort of error in a tiny transmission value would rarely mean much.

Hi Jurgen,
 I doubt you could have done any damage with a reversed connector. The worse you could do is apply a computer's output signal (high level) to the outputs of the MUN2211 buffer transistors in the AtoD module. You could look at that area, base and collector for signals with a 'scope. Also, make certain you have "pull up" resistors in either your computer, or on the Control Board.

Thanks Scotty, changed the connector signals are present now.

I connected both Mag and Phase A/D inputs in parallel for testing.

SDO of the phase AD looks fine, the graph moves up/down following the input voltage. The Mag AD only generates a single bit, it does not change with a changing input voltage, the line on the graph is stuck at 0 dBm. Looks like a damaged AD.

I mounted a male DB25 connector on the interface board. That seems to incorrect, pin 14 is grounded.

Looks like it needs a female connector.

CONFUSED, how did I get there?

Can you please confirm.

There is a signal on
Pin 14 but it gets
shorted.

I did find the relays at Newark, and saw that they would actually come from Farnell, but I didn't realize they were the same company. I did notice the handling charge--$20 on a $3 relay. So I kept looking. If the wait for them from Future Electronics is only a couple of weeks, that will be fine.

Omron now has a relay with comparable specs, but it is priced at $45. These HF3 relays are a steal.

Digi-Key has some 75 ohm relays and some non-12V 50 ohm relays, but no stock on 12V 50 ohms. That one is perfect for us because it can operate on 10V and takes so little current (10 mA) that if you are using just a few relays there is no need to bother with latching. The 5V relay uses 28 mA, which might also be acceptable but makes you think that maybe you should be doing latching.

Unfortunately, that one is a 75 ohm version, and they don't seem to have any 50 ohm relays.

I should qualify my previous response. I am really big on having sources and loads have 50 ohm impedance in many situations. But what happens if you use a 75 ohm relay at 10.7 MHz? If the signal path within the relay is 1", the relay return loss is still better than 30 dB (measured re 50 ohms). That's normally pretty good. At 100 MHz, the return loss is 14 dB. For many purposes, that is inadequate. But in this case I am switching between reflection and transmission, and in both cases the DUT is separated from the relay by a buffer amplifier. The fact that the relay has return loss of 14 dB instead of infinite dB does not amount to a hill of beans, because the DUT cannot see the relay. Or, it sees it through a glass, darkly. So a 75 ohm relay is just fine.

7492. ADC trouble shooting

Yahoo group: spectrumanalyzer (2011)
Date: 2011-01-24 03:26:26 UTC
From: pzerkel
Topic: 7492 Message: 7492

I am seeing about 1.8v on U2 pin 3 (actually most measurements have been at J1). From the Test-as-you-build page it looks like I should only be seeing about 30 millivolts.

U3 pin 3 (J2) is similar but higher at about 2.7 volts.

I have ~4.96 volts at U2-1,2,7, and 8 and same at U3-1,2,7, and 8.

I am reasonably certain that there are no shorts between those pins and pin 3. If there was I'd expect to see 4.9 volts instead of ~2 volts.

I am not sure where else to look. At this point do I assume I did something to fry the AD7685's? OR is there something else to look for?

These tests have been with nothing connected to J1 or J2.

Use a different voltmeter (or scope) to test those two points. If the results are different, it would say that the different impedance of the voltmeter is creating a different load for those points. This would say that your "short" between pin 3 and pin 2 (or another pin connected to Vcc) is a "smudge" of leftover solder paste or other contaminate.
 This is not an uncommon occurrence when using solder paste or flux. Cleaning after soldering is of utmost importance.

The AD7685 has ESD diodes on its + input, one running to +5 and one running to ground. With nothing connected to the input connector, the voltage at the + input will be the result of voltage division of the two reverse-biased diodes. When you attach the voltmeter, of course, its impedance will reduce the voltage. If you have a very high impedance voltmeter, it would be possible to measure any voltage from 0 to 5, depending on the relative impedance of the diodes.

Measuring the voltage with the input connector open doesn't seem to mean much. It seems to me that the only thing that matters is that the voltage at the + input be very low--such as below 1 mV--when the input connector is attached to a resistance of something like 10k (I think that is the PDM output resistance).

Hi Sam and All,
  It may not seem important that these AtoD inputs be extremely high impedance, but it is. This because we are not driving these inputs with low impedance source voltages. For example, the PDM source R is 10 K ohms.

 Here is the rationale:
Let's say the Phase AtoD had enough "filth" on the circuit board to create an impedance of 1 Meg ohm to +5volts. (If the input were measured with a voltmeter that had an impedance of 1 Meg ohm, the measurement would be +2.5 volts, referenced to ground.)
  Now, let' s say this Phase AtoD input were connected to the output of the PDM. The PDM is measuring 0 degrees. The PDM output should be 0 volts. Since the output has a 10 K ohm series resistor, this would create a "voltage divider" action between the PDM and the Phase AtoD input. That is, 10k to 0v and 1 Meg to +5v. The actual voltage on the input of the Phase AtoD is not 0 volts, it is +0.049505 volts, due to the voltage divider. The Phase AtoD would convert +0.049505 volts. The calculated phase would then become 360deg x .049505v/5.0v = 3.56 degrees. As you can see, this is a large error.
  If the PDM were measuring, say, 350 degrees, this error would be much smaller. This is because the source voltage is very high (+4.86 v) and would create a lower voltage drop across the 10 K ohm source resistance.
  Any error can be eliminated by guaranteeing extreme cleanliness of the AtoD inputs. This is the basis for the test on the web page,
http://scottyspectrumanalyzer.com/testingslim.html
Paragraph, "AtoD Module" is a good test. However, it assumes that the measuring voltmeter has an input impedance of somewhere between 1 Meg and 10 Meg ohms. This should be enough to "pull down" any voltage division created by the internal protection diodes.

This test would not normally be run if the MSA worked from the "get-go", but would be if there were an indication of a "strange" measurement. And pzerkel is definitely getting a strange measurement.

Topic: 7492 Message: 7497

I don't doubt that we need the ADC to have high input impedance. But if someone happens to measure the DC voltage at the input with a very high quality voltmeter with high impedance, they may think they have a problem when they really don't.

In your example of 1 Meg leakage resistance, if the the input were loaded with 10k, then 50 mV would appear at the input, which, as you say, would be a problem. Without the 10K load, the reading would depend entirely on the voltmeter impedance. It just seems like a better test to me to place the 10k resistor and then measure. Or, if the voltmeter can't measure 1 mV, use a 100 k resistor.

If the reading of 2.7 volts is not with a very high impedance voltmeter, it certainly indicates a problem. I'm always paranoid about flux residue, so I put some flux on a PCB and measured its resistance. I used regular flux, not No-Clean, because the No-Clean supposedly is not very conductive. Try as I might, I could not get any resistance reading for the flux, on a meter that should register as high as 100 Meg. I even tried laying the probes parallel on the board as close together as I could get them. So that made me less paranoid, though there are so many different fluxes that you can't draw any grand conclusions from this experiment.

Of course, if you use the hot air method with solder paste, it is possible to have tiny solder balls remaining on the board between the pads. I found that if you heat the board a few extra seconds after it appears that everything is done, it seems to eliminate almost all of those. I clean the board with alcohol and a toothbrush (wiggling, not dragging, the brush), but I suppose it is always possible to have something left under the IC where you can't get at it.

I'm suspicious of the ESD diodes; they may have been damaged by ESD. There have been a number of reports about bad ICs, which I also suspect are ESD problems. In all my MSA modules, and all the various accessory items, I have yet to encounter a bad IC, so I think proper precautions could eliminate these problems. I don't do anything elaborate. I have a large anti-static mat on the workbench where I do all the assembly. It is grounded to an earth ground. I stand at the workbench because my theory is that a good share of static comes from clothing rubbing on a chair or even on the workbench, or shuffling your feet on the floor. I don't use a wrist-strap, but I frequently have one hand in contact with the anti-static mat. So maybe that works, or maybe I have been lucky.

> The AD7685 has ESD diodes on its + input, one running to +5 and one running to ground. With nothing connected to the input connector, the voltage at the + input will be the result of voltage division of the two reverse-biased diodes. When you attach the voltmeter, of course, its impedance will reduce the voltage. If you have a very high impedance voltmeter, it would be possible to measure any voltage from 0 to 5, depending on the relative impedance of the diodes.
>
>

>
> Measuring the voltage with the input connector open doesn't seem to mean much. It seems to me that the only thing that matters is that the voltage at the + input be very low--such as below 1 mV--when the input connector is attached to a resistance of something like 10k (I think that is the PDM output resistance).

If the results are different, it would say that the different impedance of the voltmeter is creating a different load for those points. This would say that your "short" between pin 3 and pin 2 (or another pin connected to Vcc) is a "smudge" of leftover solder paste or other contaminate.

Well, that's what I was thinking Sam. But I respect the concepts of looking through clear glass and bountiful hills of beans.

Mouser has some availability of the Omron 50 Ohm relays. Search on G6Z-1F-A-DC12. They're a bit more but under $6. http://www.mouser.com

If the signal path within the relay is 1", the relay return loss is still better than 30 dB (measured re 50 ohms). That's normally pretty good. At 100 MHz, the return loss is 14 dB. For many purposes, that is inadequate. But in this case I am switching between reflection and transmission, and in both cases the DUT is separated from the relay by a buffer amplifier. The fact that the relay has return loss of 14 dB instead of infinite dB does not amount to a hill of beans, because the DUT cannot see the relay. Or, it sees it through a glass, darkly. So a 75 ohm relay is just fine.

The Omron's are decent relays, but their isolation is about 15 dB worse than the Tyco's. When you combine 3 SPDT relays to form a high-isolation SPDT, this difference doesn't matter because the final isolation will be excellent either way. But I'm trying to squeak by with a single relay, and that extra 15 dB will be a big help.

Topic: 7492 Message: 7500

Just a couple comments that may be relevant.

The DMM I am using is a Fluke 179. According tot he specifications page, the DC volt input impedance is > 10 M ohms < 100 pf"

I have two ADC's. I will report more details on differences when I can measure more.

As for ESD...I will just say I suspect that could be my problem. I probably should be taking better precautions.

I will work on it some more this evening and report back results.

7501. Crystal Ladder Filters

Yahoo group: spectrumanalyzer (2011)
Date: 2011-01-24 23:10:49 UTC
From: Sam
Topic: 7501 Message: 7501

I have not actually built a crystal ladder filter, but I have tested some crystals and used the results to simulate some filters. I'm looking at bandwidth in the 500-1000 Hz range. Before I started playing with the simulations, I assumed that getting a good response with a narrow bandwidth might require more crystals than for a wider bandwidth. Exactly the opposite seems to be the case, as the simulation results are very good for a 800 Hz filter with 4 crystals and a 500 Hz filter with 3 crystals. This is good news, as the smaller number of crystals obviously simplifies crystal matching and tuning of the assembled circuit.

Another interesting simulation experiment: I used 5 crystals and did away with all the series and shunt capacitors and put unity gain buffer amps between the stages. Four amps total--no amp at input and output. I made the source and load 50 ohms. Then I put a 100 ohm load at the output of each crystal. I got a very nice response with a bandwidth something like 900 Hz, and ultimate attenuation of at least 110 dB. I reduced all the crystal loads to 50 ohms, and the bandwidth narrowed to about 500 Hz. This general idea was discussed long ago, based on an HP design that varied the loads with PIN diodes in order to change the bandwidth. But it also is a nice simple design to get a narrow bandwidth which you can adjust during assembly to get your target bandwidth. For real-world crystals, the frequencies of the crystals can be adjusted to identical values with series capacitors, and there is no reason that the final response should have any ripple whatsoever.

It appears that the 500 Hz buffered filter could be done with 4 crystals and still get good response. This would require only 3 amps, which could be tiny inexpensive op amps, in order to achieve good power supply rejection. One stage could have gain to eliminate the filter loss.

Hi Sam,
As a side note, if planning to add gain within a filter, you could actually eliminate the need for the I.F. Amplifier in the MSA. Just make the total gain of the "Amplifilter" about 35 dB.

Topic: 7501 Message: 7503

That would be a good idea if all my filters had this design, but I'm only going to do it for the narrowest. It could work for wider filters, but you would have to add more crystals.

I think I have found the optimal approach: Create two 2-crystal filters. Connect them with a buffer amp. This basically doubles the dB values of attenuation at every point, without creating any resonance interaction between the two filters, so each pair can be independently tuned. Connect 50-ohm source and load, and load the two inner crystals with 50 ohms. If you like what you get, adjust the amp gain to reduce the loss. If you want a broader bandwidth, then all the 50-ohms need to be increased (which will also reduce the loss). Because the amp is in the middle, it probably can only be used to offset the loss of the first half of the filter; otherwise the second half might get overloaded.

In simulations, it appears that if a crystal is mis-tuned, the loss increases and a small bump appears on the side of the response. Mis-tuning never seems to create ripple on the peak. Ripple only arises if the coupling capacitors between each pair of crystals are too small (i.e. too much coupling). So if you see ripple, you know exactly what capacitor to adjust and which way to adjust it.

Tuning a crystal is done with a series capacitor. Reducing the capacitance increases the crystal frequency. The idea is to get all crystals to the same frequency. If they are close to begin with, maybe no tuning is required.

The circuit does not seem very sensitive to input and output reactances. I put shunt 10 pF on the input and saw no change.

Topic: 5081 Message: 7504

been a while sence last post, but I have moved to Florida.

looking for some advice on a spectrum analyzer.

I have a chance to buy a AILTECH 707 spectrum analyzer, it covers from 1 Mhz to 12.4 Gig. what I need to know is does anyone know of this device and will I be able to use it to test the vatiuos stages and cavity filter for the one we are building, mine is still packed away and want to get back to finishing it.
thank you.

I made up a SMA connector with two 22K resistors in parallel.

With that connected to the magnitude J1 jumper I get right at 1 mv at J1 (meter waivers between 0.7 and 1.1 mV).

I made up a very simple voltage divider with 3 AAA batteries and a single 25K pot. At first I was getting a magnitude trace which trended up and down as the potentiometer was adjusted (but it was not a straight horizontal line ever).

Now the magnitude trace is not moving at all. It is a straight line at the bottom of the graph.

I removed both AD7685s and moved the one that was in the phase position to the magnitude position... Still nothing on the graph.

Anything else to try before I order two more AD7685s?

Did you look at the serial data out. I just experienced something similar, initially my trace was stuck at the bottom and then for what ever reasons it got stuck at the top after I fixed a connector problem with my parallel interface.
Only a single bit changed. I also notice that the input pulled the applied voltage from a high impedance source to the positive.
I replaced the A/D and now it works fine.

Jurgen

Topic: 7492 Message: 7507

1 mV is a bit higher than I expected, but I don't know that it would cause any problem. But it is odd that it would jump around, and also odd that the display line was not level. So a bad IC seems likely. I suggest trying one or both ICs as the phase ADC. You should be able to generate a moving line there as well. The fact that the line suddenly dropped to the bottom makes me suspicious of communication from the latch, since neither IC now works. You might check the toggling action on the latch pins.

If you apply your variable voltage to the phase ADC, be aware that there will be some crazy action at the lowest and highest voltages that will look like massive noise. For example, at 0V the MSA will read that as 0 degrees, invert the non-existent PDM to get out of the dead zone, and then read 0 degrees again, add 180 to account for the inversion, and display a final value of 180 degrees. At the next point, it will repeat the process but the PDM will end up in the non-inverted position, so the final value will be zero. The display will bounce back and forth between those values until you raise the voltage high enough to be out of the dead zone, at which time the display will become a flat line at one of two possible values (depending on the final state of the PDM inversion). That line will then move up and down as you vary the voltage, until you get into the dead zone (below 1V or above 4V, as I recall).

Revisiting ESD: It's nice to be able to test module by module, but be aware that when you have the control board and ADC module lying on your benchtop, they are far more exposed than when they are enclosed in the MSA case. You could zap a latch by simply touching the wiring between the modules if static discharges into the wires.

Re: ADC trouble shooting

Sam,

Is it safe to assume that if the control board is still passing all the tests, then the latch pins are okay? I made up a little board with 8 LEDs and resistors and a nine-pin connector to test the CB with. It still seems to work as expected when running the CB test program.

It is possible to have a latch output that is slow, or doesn't produce full voltage, but those are hard to test for. You should check that the ADC output is toggling while a scan is active; if it is, it is probably getting the necessary commands. (Maybe you need to have some input voltage, so it is not outputting all zeroes.)

You should also use the CB tester to see whether the MSA can read the ADC outputs; you probably need to disconnect the ADC and connect those parallel port lines to 0 or +5 (you should have pull-up resistors on those lines on the control board, so if you connect nothing the voltage will be +5). Scotty's CB tester and the one in the beta software can test read the "control" lines that the ADC connects to; I don't recall if my tester does that.

Hints for MSA trouble shooting

Please be aware that all your various mains powered sources and test equipment are usually FLOATING.

These units on their own can all be at various nasty AC/DC potentials and many contain mains filter caps etc.

BEFORE YOU START:

Ensure all PC and power suplies and test equipment "OV + "earths" are all joined with separate good earth strap.

DO NOT rely on the MSA to become the only common earth point when every is connected.

Otherwise when you unplug/plug various modules you make/separate these "floating" earths too.

Murphy's law states that with any connector the signal pins always make first before the GND pins and disconnect last.

Regards

Len Spyker

7512. Announcing an MSA Filter plus GROUP BUY

Yahoo group: spectrumanalyzer (2011)
Date: 2011-01-29 02:01:24 UTC
From: jghbeta
Topic: 7512 Message: 7512

Hi everyone,

I am organizing a PCB-only Group-Buy which is described in detail below. As you will see, there is much more than filters but RBW filters are the main theme.

2 each 5 pole filters
1 each 4 pole filters
1 each amplifilters
2 each ceramic filters
2 each low pass filters
1 each updated video filter switch board
1 each updated W1JGH power meter
1 High isolation SPDT
1 VHF Transmission/Reflection switch
1 AADE accessory board to measure SMDs

All filters have provisions to utilize surface mounts trimmer capacitors. The series TZY2 trimmers from Murata (available at Digikey) has prices comparable to the good quality ceramics., but the boards have pads that also allow for the larger 1/4 inch sizes. The ceramic filter pcb is a variation of the one available in October's group buy, it is slightly larger and also includes pads for trimmers. This board is well suited for wider bandwidths.

The amplifilter is Sam's new addition to the arsenal. It will house 4 crystals with a buffer in the middle. A very intriguing experimental design.

The power meter auxiliary board is designed for the MiniCircuits ZX47 series power sensors. It simplifies wiring by incorporating the calibrating pot, led and switch in the board itself. I'll have a set of assembly pictures in the next few days.

There is an updated PCB for the video filter switch incorporating the latest refinements from Sam W.

The SPDT is Sam W design for a generic PE4251 filter that may be used as a band or a transmission/ reflection switch. It has very good isolation up to 1GHz (90 dB)

The VHF transmission/ reflection bridge is Sam W implementation of an S-parameter test set that should be good through 300 MHz or so, and should be superb to 100 or 150 MHz. It contains a buffer amp, a bridge, and a relay to select transmission or reflection. It's not really a full-blown S-parameter test set because it cannot reverse the DUT. It should be accurate without the use of 6-term or 12-term calibration, and any mechanism to reverse the DUT screws that up. To use it, the DUT is connected between the DUT port of the bridge and the input of the buffer amp. This lets the DUT see solid 50 ohms on each end regardless of the relay setting. The relay selects the bridge output for reflection and the buffer amp output for transmission. We will publish the schematics in a couple of days.
The AADE accessory board l fits in the terminals of the AADE L/C meter. It may be left permanently in place without interfering with normal operation. By simply placing the SMD

device in the proper position and holding it in place with a transparent plastic strip (held down by scotch tape) will let you determine their values. It will allow for parallel and series combinations of components.

+++++++++

I am preparing a document with pictures, schematics, etc. There maybe a couple of additional boards from Sam that may be added. Any suggestions are most welcome.

I need expressions of interest from some brave souls and after that we will move quickly to the actual ordering. So that we don't overload the mail system, please address them to me directly: jghalpha(at)gmail(dot)com. Based on the number of interested parties I should be able to get a quote. My estimate is that this board will be around 30-40 bucks.

Hi i wander about, can i redo my TARGUS USB Dongle
and make it a spectrum analyzer?

This TARGUS is a AMW07 with bellonging USB dongle at 2.4GHz!

Do i need reprogramming, by redo firmware here?
I that case, what is the FIRMWARE i need and,
what chipset is it on this dongle?

The question is not very clear. If the question is taken literally and is asking whether the Targus can be used as a spectrum analyzer, the answer is no, because it is just a communication device. If the question is whether the Targus can be used as an interface to the MSA, the answer is "possibly". I don't know much about it, but once USB is implemented on the MSA, perhaps a Targus device could be used on each end so both the MSA and PC would think they are communicating by USB, but there would be a bluetooth link involved in the middle. However, I suspect it would be slow.

No, means no to the first question. The second question becomes irrelevant then.

I have an old spark plug and a couple of nuts in my junk box. Can I build a car with them? What kind of gas should I use?

Jim.

From: Sam
Topic: 7512 Message: 7520

Just wanted to add some thoughts on a couple of these boards.

The "amplifilter" (I'm using Scotty's term, though the gain is not enough to replace the IF amp) has two crystals, then a buffer amp, then two more crystals. Hopefully it will make a very narrow RBW filter (400-800 Hz?) that will be fairly easy to tune.

The "VHF Transmission/Reflection Set" combines a bridge and buffer amp with a transmission/reflection switch. "VHF" is intended to convey that it does not cover the full range to 1 GHz, though it does also cover far below VHF, to 250 kHz or so, depending how big you make the capacitors. It could also do a nice job of displaying return loss from 250 kHz to 100 MHz with just a spectrum analyzer with TG.

The SPDT is a compact high-isolation solid-state switch. I have not built this exact one, but a similar switch performed very well. It uses 3 very cheap PE4251s.

The video filter board is the same as the one I am using now, with fixes to a couple of traces and pads.

Sam W.

> 2 each 5 pole filters
> 1 each 4 pole filters
> 1 each amplifilters
> 2 each ceramic filters
> 2 each low pass filters
> 1 each updated video filter switch board
> 1 each updated W1JGH power meter
> 1 High isolation SPDT
> 1 VHF Transmission/Reflection switch
> 1 AADE accessory board to measure SMDs
>
> All filters have provisions to utilize surface mounts trimmer capacitors. The series TZY2 trimmers from Murata (available at Digikey) has prices comparable to the good quality ceramics., but the boards have pads that also allow for the larger 1/4 inch sizes. The ceramic filter pcb is a variation of the one available in October's group buy, it is slightly larger and also includes pads for trimmers. This board is well suited for wider bandwidths.
>
> The amplifilter is Sam's new addition to the arsenal. It will house 4 crystals with a

buffer in the middle. A very intriguing experimental design.
>
> The power meter auxiliary board is designed for the MiniCircuits ZX47 series power sensors. It simplifies wiring by incorporating the calibrating pot, led and switch in the board itself. I'll have a set of assembly pictures in the next few days.

>
> The SPDT is Sam W design for a generic PE4251 filter that may be used as a band or a transmission/ reflection switch. It has very good isolation up to 1GHz (90 dB)
>
> The VHF transmission/ reflection bridge is Sam W implementation of an S-parameter test set that should be good through 300 MHz or so, and should be superb to 100 or 150 MHz. It contains a buffer amp, a bridge, and a relay to select transmission or reflection. It's not really a full-blown S-parameter test set because it cannot reverse the DUT. It should be accurate without the use of 6-term or 12-term calibration, and any mechanism to reverse the DUT screws that up. To use it, the DUT is connected between the DUT port of the bridge and the input of the buffer amp. This lets the DUT see solid 50 ohms on each end regardless of the relay setting. The relay selects the bridge output for reflection and the buffer amp output for transmission. We will publish the schematics in a couple of days.
> The AADE accessory board l fits in the terminals of the AADE L/C meter. It may be left permanently in place without interfering with normal operation. By simply placing the SMD device in the proper position and holding it in place with a transparent plastic strip (held down by scotch tape) will let you determine their values. It will allow for parallel and series combinations of components.

As rescue RDFer i did find this Advantest 3361A good to find a transmitter as well,
I put in low frequency, and high frequency, in that frequency area we know the transmitter is repported,
and monitor them spikes, and try to sepparate the transmitter from
others on this spectrum-band!

When we find this transmitter, we can listen to it and confirm if it is the right transmitter,
then follow the spike here, and find the direction by monitor the strenght of this spike,
as higher the spike is, as closer the transmitter is!

We just use a vertical yagi here,
do not need to use an antenna array!

Date: 2011-01-30 14:49:39 UTC
From: Sam
Topic: 7512 Message: 7528

Other than resistors/capacitors, it uses
1 OPA842 op amp, SOT-23 package
1 BLM21AG102 ferrite bead
1 L4931CD80 8v LDO regulator
2 Pulse PE-0805CM681JTT 680 nH inductor

The inductors are for 10.7 MHz for 10.1 MHz use the 750 nH equivalent. All these parts are available at Digi-Key, except you can get the op amp at Mouser. I was intending to find one that Digi-Key carries, but haven't done so. The key thing is that it be available in SOT-23 and can operate at 8V with reasonably flat gain to 11 MHz with gain of 4. This probably takes gain-bandwidth product of at least 200 or 300 MHz.

It can use 4 of the trimmers that Jim mentioned, but I am hoping the tuning will be simple enough that trimmers aren't required. If adjustment is required, I'm hoping it can be done by one-time adding or removal of a parallel cap.

As stated in the group intro, this site is for Scotty's Spectrum Analyzer and "similar projects", meaning home-brew analyzers. It is not for broad, open-ended questions about commercial equipment, for which you should consult the operating manual.

I might also add that it rankles me when people expect detailed answers to broad, vague questions into which they have put a Twitter-level of thought. That thought level is often quickly identifiable by consistent failure to capitalize "i". By this I do not mean to discourage broad introductory questions about the MSA.

7531. High impedance bridge

Yahoo group: spectrumanalyzer (2011)
Date: 2011-01-30 16:20:47 UTC
From: Sam
Topic: 7531 Message: 7531

I have been fascinated by op-amp based bridges, in part because they can perform nearly perfectly below some frequency (somewhere in the 10-50 MHz range) and can perform very well above that. One thing this lets you do is display return loss graphs using just a spectrum analyzer + tracking generator. In fact, you don't even need a tracking generator, if you have a noise generator or plain-old swept-frequency-generator. Or, with the MSA/VNA, scans can be made with referece calibration, much simpler than OSL.

In some cases, it would be handy for the bridge to have a reference impedance different from 50 ohms. 75 ohms is an obvious possibility, but there are also situations where a much higher impedance would be appropriate. For example, you could get more accurate measurements of MCF filters by using higher impedances. Especially below 30 MHz, many circuits might have impedances much higher than 50 ohms. Likewise, there may be circumstances where it would be nice to have a very low impedance bridge.

I have designed a bridge whose reference impedance can be changed simply. Different high impedances could be selected by changing a single resistor. This single resistor approach will work for 50 ohms and higher. Lower impedances require changing a couple of resistors. The idea of changing resistors probably only works if you do so only occasionally, or if you create some simple switching method or allow plug-in resistors. The latter approach would work, but the goal of "perfect performance" probably limits the frequency range to <10 MHz or so.

I am interested in whether this sort of thing actually appeals to anybody. If so, this board could be added to Jim's board.

Sam W.

Cato,

The spectrum analyzer group is dedicated to a home brew spectrum analyzer that was designed by William (Scotty) Sprowls

http://www.scottyspectrumanalyzer.com/index.html

I do believe that many members will answer questions if they can but the group centers around this particular project.

There are other groups that discuss various types of spectrum analyzers such as the elect-inst group and the advantestinstrument group.

Best Regards

Dan Ellis

Sam,

There is more than enough room in board to add the bridge.
As an update, there are 13 users from all over the world who have expressed an interest. So, numbers wise, the board is a go. I will suspect that we willl end up in the 20's.

Correction. Mouser is now out of OPA842. OPA695 would be a good substitute. Mouser has them; Digi-Key does not. OPA356, which Digi-Key has, would likely work, and with that one you could use the normal ua7805L regulator, which the PCB will also accommodate. (In fact, with the OPA356, you have to use the 5V regulator; 8V would blow it.)

> The inductors are for 10.7 MHz for 10.1 MHz use the 750 nH equivalent. All these parts are available at Digi-Key, except you can get the op amp at Mouser. I was intending to find one that Digi-Key carries, but haven't done so. The key thing is that it be available in SOT-23 and can operate at 8V with reasonably flat gain to 11 MHz with gain of 4. This probably takes gain-bandwidth product of at least 200 or 300 MHz.
>
> It can use 4 of the trimmers that Jim mentioned, but I am hoping the tuning will be simple enough that trimmers aren't required. If adjustment is required, I'm hoping it can be done by one-time adding or removal of a parallel cap.

Hi folks,

What is the easiest method to add USB to an existing parallel port control board? Expense is not as much an issue as trying to rewire or re-code to accommodate that.

From: Sam
Topic: 7416 Message: 7537

You can buy an assembled Cypress board on eBay. I bought one for about $30, though I have yet to do anything with it. You just need to connect the appropriate pins of the Cypress to a male parallel port connector, and plug that into the control board. I understand that the pin assignments are in Dave's documentation on this site, and that Jim has gotten his MSA to work using this approach. Operation of switches other than the RBW switch is not yet supported in USB, but hopefully will be soon.

Hi Fan,
Here is my understanding. There will be one USB board. It is already designed and in use for other projects. It has the standard USB input connector, and output pin connections.
 If this board is used to completely eliminate the SLIM Control Board, the wiring will connect from this USB Board to the SLIM Modules.
If this board is used to control the SLIM Control Board, it will wire to a male, DB25 connector that will plug into the female of the SLIM Control Board.
 The software will have the provision to be "told" to use "USB Only" or "USB/Parallel".
The software is still in the beta test mode.

The board I bought in eBay was the EZ-USB FX2XLP. It has a 128 pin Cypress chip and more pins and functionality than required for the MSA as it stands today. It works well if set up following carefully Dave’s instructions. A hint: use individual connectors for each wire. This allows you to go from the control board to the USB board easily. I am currently running from the control board because of the lack of implementation of the P4 switches (except the RBW).

Jim

Yes I went a similar way. I built a Cypress board according to Dave's design and put it in a small plastic box with a USB connector one end and a short length of ribbon cable and a male DB25 on the other. This allows me to run either USB or parallel.

Ron, VK7ZRO.

You just need to connect the appropriate pins of the Cypress to a male parallel port connector, and plug that into the control board. I understand that the pin assignments are in Dave's documentation on this site, and that Jim has gotten his MSA to work using this approach. Operation of switches other than the RBW switch is not yet supported in USB, but hopefully will be soon.

G'day Jim,

I've a spare EZ-USB PCB that could be used as the controller. Where do I find Dave's instructions?

Hello all! First time poster!

I am an EE student studying the design of a zero IF spectrum analyzer.

All papers I've read so far talk about spectrum analyzer designs upconverting to a high IF frequency then downconverting. I know that the main problem for zero-IF spectrum analyzers is flicker noise. Assuming I don't care too much about the sensitivity of my spectrum analyzer, is there anything that is prohibiting me from actually using a DC IF frequency?

Thank you for your time!

Yes it is possible.

The VNWA2 by DG8SAQ can be used to provide a simple SA function using a 'DC IF'

See :- http://www.sdr-kits.net <http://www.sdr-kits.net/> for further information.

A "Zero IF" SA? Sure, as long as you have a broadband frontend and a very(!) wide band A/D converter with more than 16 bit resolution (16 bits gives you 90-ish dynamic range).

You can deal with "known" and predictable spurs in your DSP bu tthe frontend A/D will be a hard ut to crack unless yo design a high speed D/A with any of the fastest FPGA's.

If you accept the Zero IF SA to be a "sampling" SA, you can sample around half of the D/A's banwidth but if you want a "normal" SA, you have to go down a bit.

But be aware - you really need a shitload of number crunching power - so forget any PIC's or Atmel's doing the DSP'ing for you...

Make a broadband front > get the fastest A/D available > get the fastest and mightiest DSP processor available > Make your own display, don't even think on the word "USB"...

When you are eady with all this, then you'll understand why we design SA's the way we do...

The VNWA2 is a 1 (one) IF design. The IF is below 30KHz as a standard sound cip (USB) is doing the work and the rest is done in the software.

Off the cuff, here are some thoughts:

For a 0Hz IF SA, you would generate exactly the signal you want to view, mix it as the LO with the input, and evaluate the DC result. However, the DC level will depend on the relative phase of the LO and input signal. To resolve this problem, you need to use an IQ approach where you mix the input with the LO in one mixer and with a 90-degree-shifted version of the LO in another mixer and evaluate both DC levels. There are ICs that handle the IQ mixing within certain frequency ranges, but I'm not sure how suitable they are for generating DC outputs.

You will get false signals if spurs or harmonics of your LO signal match the frequency of signals in the input. Even if your LO signal does not contain harmonics, they will effectively be generated in the mixer. The spur/harmonic problem will limit the dynamic range if the input contains significant signals in addition to the one you want to look at, but maybe it still leaves enough range for your purposes.

The harmonic problem also exists for up-converting SAs, but the harmonics are well above the desired input range so it is feasible to filter the troublemakers out of the input. Or, you can filter out the lower frequencies and purposely target the harmonics.

Also, if you want to cover a broad range such as 0-1 GHz, generation of the LO signal will require that you use a high frequency VCO, such as 1-2 GHz, and downconvert it. So using a 0 Hz IF may not save you as much trouble as you hoped.

The DC produces a signal at the "coupled port" that is a fraction of that running from the "In" to the "Out" port. For a bridge, you don't care about the forward signal; you want a sample of the reflection. Therefore, you connect the TG to Out, the DUT to In and the MSA input to Coupled. If the DC is a 20 dB coupler, the signal at the MSA input will then be 20 dB below the reflection traveling from the DUT back to the DC In port. (You don't care exactly what the fraction is; that is dealt with automatically in Reference or OSL calibration.)

For DUTs with both input and output, you terminate the output with 50 ohms. Or, if you have a Transmission/Reflection switch you can connect the DUT input to DC In, as above, and connect the DUT output to the switch's transmission input, and the DC coupled port to the switch's reflection input. The switch output goes to the MSA input. The switch can then select the DUT output to measure transmission or the DC Coupled port to measure reflection. That selection is done automatically in the beta software when you switch between Transmission and Reflection modes.

Hello Dan,

I think I am misunderstanding some key fundamental. I am confused why an extremely fast A/D is needed. If my IF was say, 10 MHz, then I would need a sampling frequency of at least 20 MHz (as I understand the nyquist theorem). With that reasoning, my intuition tells me that a zero-IF or near-zero-IF can absolutely make due with a slow ADC.

When you call a design "Zero IF", I read it exactly for what you call it, no IF stage. The zero IF designs have just a filter and attenuators at the front end before the A/D. The A/D takes in the full bandwidth of the SA, not a 10MHZ fraction of the band as when you have a copule of IF stages and mixers.

The Zero IF SA have no mixers either.

But as you describe it here, you mean a standard SA with low frequency IF.

That's a different animal all together! Look up DG8SAQ and VNWA2.
It's a VNA design (with SA) baed around the low frequency concept you probably mean.

The VNWA2 use two DDS'es, set apart by a few KHz. The two DDS'es are there to make a 360 degree phase readout possible.

Now to Nyqvist. Sampling at double the frequency will theoretically mean you can measure with half the sampling ratye as your bandwidth maximum. Yes, but it's really not good enough except for repetitive signals. Look at the important word "Sampling". Compare this with a sampling oscilloscope. You read - 8GHz bandwidth, and then they hide "repetitive signals" in the small print.

Use Google to find the manual for the DS800 Oscilloscope from IBZ electronics. This is a cheap 8GHz sampling USB oscilloscope. When using presampling, you can measure 4GHz repetitive signals, not bad for 399 U$

So, watch your choice of words... Zero IF is not "near zero IF" unless you write so.

The big boys use YIG controlled oscilloscopes with both YIG oscillators as well as YIG filters for the rathere extreme prestanda they advertiose. Unfortunately - it comes with a price tag.

If you really want to do something regarding SA's. Build a FPGA based A/D and design a real "Zero IF" (or rather "No IF) SA around it.
Also, the use of DC can mean two things in this type of groups... DC as in Direct Current but also as Direct Conversion. A "No IF or Zero IF" Sa is a Direct Conversion design.

Zero IF receivers (a/k/a direct conversion receivers) do use an IF, but it is at zero Hz. Low IF receivers use a positive IF. Either way, some down-conversion is done with an LO and mixer. That's the terminology used by the chip manufactures who make the ICs that do the conversion. I don't know what the terminology would be if you went directly to digital. Such a technique would indeed use "no IF", but the term "no IF" wouldn't necessarily imply digital.

I forgot to add that if you want to use a YIG to generate an LO signal for your SA, check out the Stellex control boards available on eBay. They usually come with a YIG somewhere in the 8-10 GHz range, and cost about $60. For another $50-75 you can buy a lower frequency YIG on eBay. Search for the web site of John Miles, who explains how to use the Stellex boards to run your YIG. You just have to connect the board to the parallel port and use either his software or that from National Semiconductor--it's all a matter of programming an LM2326 IC, just like the MSA uses.

That's the terminology used by the chip manufactures who make the ICs that do the conversion. I don't know what the terminology would be if you went directly to digital. Such a technique would indeed use "no IF", but the term "no IF" wouldn't necessarily imply digital.

Scotty,
I would like to add the step recovery modules to the groupbuy board that I have underway.
Any updates or suggestions?

Hi Jim,
 I have not made any mods or changes to the Multiplier. I do want to, someday.The idea here is for this new SLIM to fully replace the PLO 2 without any other components. It would use the same multiplier design as a basis, but with the following additions:
1. Size would be 1.2 x 2.4 (2U). This would be the same size as the SLIM PLO2, which it would replace.
2. Add an on-board ceramic filter that will pass 1024 MHz. This would replace the 2 stage cavity filter.
3. Add post filter splitter and 2 ERA-33 amplifiers for two outputs.
Scotty

Jim,
Here's a suggestion, based on my experience playing with the SRD multiplier years ago. If you use a 6"-12" coax between the diode output and a high pass filter (designed to reflect the lower harmonics), and place a 0.5-5 pF piston capacitor shunt to ground at the filter input, tuning the capacitor has a dramatic impact on the output power at your desired frequency. I managed to get 10 dBm this way with no amplifier. (I used a different design than Scotty's, but my design was probably no better than his.) You can view this as tinkering with the phase of the reflection of the low harmonics. I prefer to view it as altering the shape of the diode pulse. For high harmonic numbers (like 16), the harmonic content of a pulse is extremely sensitive to the shape of the pulse until you get to a very narrow pulse width. A small change in shape can take you from high power to no power for a given harmonic. Somewhere, I have a document on the mathematics of that.

As I recall, Scotty did a similar thing, but took it out of his final circuit because people might not have the equipment to watch the effects of their tuning. But once you have the MSA, it's easy.

Ahh I apologize for my confusion. Thank you for pointing out my vague word choice.

I see that the VNAW2 uses a low frequency IF, but why not exactly an IF of 0 Hz? Besides flicker noise affecting my sensitivity, what is keeping me from using a 0 Hz IF? This would, in theory, eliminate image frequencies. Also, for the sake of simplicity, let's assume that my spectrum analyzer will analyze signals from 1 MHz to 100 MHz.

Also, I was always under the impression that 0 Hz meant direct current DC?

Sam,

Is it necessary to "generate exactly the signal I want to view"? Say I want to analyze signals from 1 MHz-100 MHz. Wouldn't I just need an LO that sweeps from 1 MHz - 100 MHz? The mixer difference frequencies that match the input signal's frequencies would then all downconvert to 0 Hz IF.

>
> Off the cuff, here are some thoughts:
>
> For a 0Hz IF SA, you would generate exactly the signal you want to view, mix it as the LO with the input, and evaluate the DC result. However, the DC level will depend on the relative phase of the LO and input signal. To resolve this problem, you need to use an IQ approach where you mix the input with the LO in one mixer and with a 90-degree-shifted version of the LO in another mixer and evaluate both DC levels. There are ICs that handle the IQ mixing within certain frequency ranges, but I'm not sure how suitable they are for generating DC outputs.
>
> You will get false signals if spurs or harmonics of your LO signal match the frequency of signals in the input. Even if your LO signal does not contain harmonics, they will effectively be generated in the mixer. The spur/harmonic problem will limit the dynamic range if the input contains significant signals in addition to the one you want to look at, but maybe it still leaves enough range for your purposes.
>
> The harmonic problem also exists for up-converting SAs, but the harmonics are well above the desired input range so it is feasible to filter the troublemakers out of the input. Or, you can filter out the lower frequencies and purposely target the harmonics.
>

What you describe is what I meant. At any one instant, you are analyzing one frequency, which is what I meant by the signal you want to view. So you generate exactly that frequency for your LO. After you analyze that frequency, you move to the next, etc. The mixing process at each frequency produces the 0 Hz IF that indicates the strength of the input signal at that frequency. 0 Hz is direct current, though what you really get is some bandwidth around 0 Hz, with the negative frequencies effectively folding over on top of the positive frequencies. Having both the I and Q measurements lets you sort things out. If you want to have selectable bandwidths, I think you have to either have selectable filters, or use a wide filter and resolve things digitally with multiple I and Q measurements and FFT. Frankly, that's about all I know (or maybe more than I know) about the I/Q process.

A VNA is simpler than an SA in one respect: images are not a major issue. The only signal in the VNA input is the test signal reflected by or transmitted by the DUT, unless there is a foreign signal coming in from an antenna being tested, for example. The only image problem presented by the test signal results from a spur that is separated from the main signal by exactly the right frequency difference. This makes it feasible to use an IF such as 30 kHz. In an SA, though, a 30 kHz IF would result in every input signal appearing twice, where the LO equals the signal frequency +/- 30 kHz. That is, unless you can filter one of those out, which is difficult for such a low IF value.

Therefore, a 30 kHz LO is very workable for a VNA, but not so much so for an SA. On the other hand, both the VNA and SA have the harmonic issue with a 0 Hz LO, in that input harmonics of the target frequency create false images. So, for the VNA, it makes sense to avoid the 0 Hz IF, since a low, non-zero IF can work fine.

The harmonic problem can be resolved by digital processing of the IF, however. See the N2PK VNA Yahoo group regarding CDS (correlated double sampling).

Hackurate,
 This is my 2 cent's worth. What you are describing is called synchronous detection. It has been around since pre WW 2. It was used for detecting the modulation of a signal without converting the signal to an Intermediate Frequency. It still converts the input signal to "0" Hz, using a mixing process. It was never intended for SA use because as Sam states, a "same frequency" phase lock is necessary. It is simple for single frequencies or several that are close together. Say 5%. Exceedingly difficult for wide band (1-100 MHz), although possible.
 Read up by googling "synchronous detection'. I promise you, you will pull your hair out. After a few days you might say, "Gee, the MSA doesn't look so bad, after all."
Scotty (with grins)

What you describe is what I meant. At any one instant, you are analyzing one frequency, which is what I meant by the signal you want to view. So you generate exactly that frequency for your LO. After you analyze that frequency, you move to the next, etc. The mixing process at each frequency produces the 0 Hz IF that indicates the strength of the input signal at that frequency. 0 Hz is direct current, though what you really get is some bandwidth around 0 Hz, with the negative frequencies effectively folding over on top of the positive frequencies. Having both the I and Q measurements lets you sort things out. If you want to have selectable bandwidths, I think you have to either have selectable filters, or use a wide filter and resolve things digitally with multiple I and Q measurements and FFT. Frankly, that's about all I know (or maybe more than I know) about the I/Q process.

Sam W.

>

> Sam,

>

> Is it necessary to "generate exactly the signal I want to view"? Say I want to analyze signals from 1 MHz-100 MHz. Wouldn't I just need an LO that sweeps from 1 MHz - 100 MHz? The mixer difference frequencies that match the input signal's frequencies would then all downconvert to 0 Hz IF.

>

> --- In spectrumanalyzer@yahoogroups.com, "Sam" <swetterlin@> wrote:

> >

> > Off the cuff, here are some thoughts:

> >

> > For a 0Hz IF SA, you would generate exactly the signal you want to view, mix it as the LO with the input, and evaluate the DC result. However, the DC level will depend on the relative phase of the LO and input signal. To resolve this problem, you need to use an IQ approach where you mix the input with the LO in one mixer and with a 90-degree-shifted version of the LO in another mixer and evaluate both DC levels. There are ICs that handle the IQ mixing within certain frequency ranges, but I'm not sure how suitable they are for generating DC outputs.

> >

> > You will get false signals if spurs or harmonics of your LO signal match the frequency of signals in the input. Even if your LO signal does not contain harmonics, they will effectively be generated in the mixer. The spur/harmonic problem will limit the dynamic range if the input contains significant signals in addition to the one you want to look at, but maybe it still leaves enough range for your purposes.

> >

> > The harmonic problem also exists for up-converting SAs, but the harmonics are well above the desired input range so it is feasible to filter the troublemakers out of the input. Or, you can filter out the lower frequencies and purposely target the harmonics.

> >

> > Also, if you want to cover a broad range such as 0-1 GHz, generation of the LO signal will require that you use a high frequency VCO, such as 1-2 GHz, and downconvert it. So using a 0 Hz IF may not save you as much trouble as you hoped.

The VNWA and other SDR devices use the 16 to 24 bits of a PC sound card to perform the sampling. These cards have a capacitor on the input and also some filtering to remove 50 / 60Hz and harmonics power line noise. A low frequency IF of typically 10 - 30KHz is chosen, the PC software then applies the necessary offset corrections.

Ahh I apologize for my confusion. Thank you for pointing out my vague word choice.

I see that the VNAW2 uses a low frequency IF, but why not exactly an IF of 0 Hz? Besides flicker noise affecting my sensitivity, what is keeping me from using a 0 Hz IF? This would, in theory, eliminate image frequencies. Also, for the sake of simplicity, let's assume that my spectrum analyzer will analyze signals from 1 MHz to 100 MHz.

Also, I was always under the impression that 0 Hz meant direct current DC?

7564. PLO2

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-04 00:09:09 UTC
From: radiotalk@xtra.co.nz
Topic: 7564 Message: 7564

Have just completed the assembly of boards for the VNA & started testing. Many thanks for the great project info.
I'm using the compiled V115 windows software.
I have tested from j3 IFA 10.7MHz to ADC & all appears well, input dB/mag dB step ie increasing the input gives me an increase on the Screen display. But PLO2 does not appear to be commanded to 1024MHz & U2-2 is 0v. All my PLO's are the ADF4112. Have checked all volts etc & cabling. PLO1 will return to 1013.296MHz on sweep halt.

On the compiled version V115, there is no "Show Variables" under Menu->Options?
If I try to select "4112" for PLO2 under the Hardware setup & save the file, it always defaults back to "2326" on program startup?

Do I need to install the basic version to test further?

Any help appreciated.

Chris

Hi Chris,
 Ver 115 has a bug when using the ADF 4112. We are close to releasing Version 116 and the Beta version is in the Files section. I will compile it into a .tkn file and put it in the Files section for temporary utilization. Look for it in the next few hours.

Thanks Scotty.

That V116 has certainly fixed those issues. My next issue is that the commanding appears intermittent, both PL02 & PLO1 will not always initialise unless I have an oscilloscope probe connected to the LE lines & force a "Restart" sweep.

If I recall correctly, someone else had this issue with another ADF chip series?? Was there any solution?

Thanks again for the quick compile.

Topic: 7564 Message: 7568

See message 6959 and its thread. Some capacitance or resistance to load the line should do the trick. Presently, your scope probe is adding the capacitance.

7569. Liberty Basic Purchase Problem

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-05 02:53:32 UTC
From: nealmartini
Topic: 7569 Message: 7569

All,

Three weeks ago I decided to break down and purchase Liberty Basic so I could try out the latest Beta upgrade for the MSA software. Before that I was just using the latest executable so I did not have to use the Liberty Basic program to compile.

I followed the links that come up when you try and start the Liberty Basic Trial Copy and went through the process of ordering Liberty Basic for $59 and added the option of a $10 CD version.

To date I have not received anything. The website said I would get an email telling me how to download Liberty Basic, but I never did. I thought maybe they were going to send the CD since I selected that option, but I never received anything.

I also called the telephone number listed in the pop up and was only able to leave messages. I did not receive any return calls. Incidentally, my credit card was charged with the $69 the day after I placed the order.

Does anyone know the person who supplies Liberty Basic? Has anyone been successful in ordering from the pop up that comes up when you start the trial version of Liberty Basic? Any other suggestions?

Help

Hi Neal,
The owner of Liberty Basic is Carl Gunter (or Gunther). Normally, you would download the free version from their website and when they get a payment, they supply you with the Code Key. This Key just unlocks the same code into full use. I never messed with the CD. But, I'm guessing you would get it in the snail mail, along with the Code Key.
 I suggest you email their support address, and tell Carl you are unhappy.
BTW, the executable for the new Beta is in the Files Section of our Group.

There is also an active Liberty Basic group on Yahoo; you could post a message there. In my experience, Carl has been good to deal with.

7573. MSA V116 and divide by zero error

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-05 22:40:21 UTC
From: motorol9
Topic: 7573 Message: 7573

I downloaded the new V 116 tkn file and tried to run it without any hardware connected. I get an error message saying there is a divide by zero error. Does the new software need the hardware connected for it to run ?.
Thanks
Rex

Copy of part of the error log generated.

Error log timestamp Sunday 06/02/11 08:34:50

Runtime error: Division by zero

```
Error(Exception)>>defaultAction
Error(Exception)>>activateHandler: <anUndefinedObject>
Error(Exception)>>handle
Error(Exception)>>signal
Error class(Exception class)>>signal: <'Division by zero'>
BasicRunProgram(Object)>>error: <'Division by zero'>

It should run with no hardware. Did you do anything, or did it just start up and crash? Unfortunately, the Liberty Basic error log file never provides useful information. Do you have LB, so you can run it under the Debugger? That would tell you exactly where it crashed.

7575. Board Group Buy

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-06 03:07:54 UTC
From: Jim Hontoria
Topic: 7575 Message: 7575
Attachments: 2 described; binary payloads are missing from this source WARC

Hi everyone:

Please see attached two documents: One of them contains a description of the February 2011 group buy (this very same), the other one has all the individual pcb and sch files. This group buy started as filter collection but by popular demand has grown t something larger. In summary what we have is a board consisting on the following:

2 each 5 pole filters

1 each 4 pole filter

1 each amplifilter

2 each ceramic filters

4 each lo/hi pass filters

1 step recovery diode board

1 each updated video filter switch board

1 each updated W1JGH power meter

1 each Hi-Impedance bridge

1 VGA board for log detector

1 High isolation SPDT

1 VHF Transmission/Reflection switch

1 AADE accessory board to measure SMDs

Some boards are entirely new, others are updates and a good number of them are experimental.

Read the attached documentation for further details and how to order.

(Sorry for the highlighting, I don't seem to be avble to get rid of it)

Jim W1JGH

Hi all,

Must be a few buyers for the ZEDC-15-2B-1 Directional Coupler. I note that the the price is now $19.99.

Roderick Wall, vk3yc.

The coupler which has just arived from China (after China Post held up the delivery) matches the spec as well as Sam's but, this is where I show my lack of knowledge, what connections are used for it to be used as a bridge ??

Rex,
I didn't make this clear when I put the new version 116 "spectrumanalyzer.tkn" in the Files section. It just replaces the version 115 that is normally downloaded from the web page:
http://scottyspectrumanalyzer.com/msasetcal.html
All of the accessory files must be downloaded into a common folder, including either one of the "spectrumanalyzer.tkn". Delete the version 115 "spectrumanalyzer.tkn" from that common folder before downloading the new version 116 "spectrumanalyzer.tkn" from the Files section.
Did you get an error with the version 115 "spectrumanalyzer.tkn"? If it ran ok, then the new version 116 "spectrumanalyzer.tkn" should run ok.
Scotty

7582. PDM testing using DDS1 and DDS3

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-06 20:11:46 UTC
From: davidhooau
Topic: 7582 Message: 7582

Folks,

Is it possible to test the PDM using only DDS1 and DDS3 (no mixers or PLOs)? I wondered if a similar trick using "DDS1 sweep" to test the RWB filters could be applied here.

If it is possible, could this configuration be used as a VNA for testing at IF2 frequencies?

Thanks,

davidh

hi Scotty/Sam

Version 115 runs normally. I renamed the V115 tkn file (spectrumanalyzer.tkn.old) then added the V116 file to the same directory as spectrumanalyzer.tkn. When running the program it comes up with the divide error. Swapping the 2 tkn files around by renaming them V115 runs normally again.

Hi Rex,
It is possible the file got corrupted during your download from the Files page. Throw away the one you have and download it again. If it still burps, send your downloaded copy to me via regular e-mail as an attachment. I performed the process with my WinXP computer and had no difficulty.
  By the way. Look in your common folder for the file folder called MSA_Info. Perhaps it has a problem. Throw it in the trash or rename it. Then run your "spectrumanalyzer.exe again. It looks for this folder and if not found, it creates a new one.

Hi Scotty

You got it. I deleated the MSA.Info folder and reran the setup screen creating a new one and all functions correctly. As I have only got the base specan working there were only the filter bandwidths and the filter calibration files. Don't know if that helps with the problem.

Thanks

Rex

7590. Group Buy: The deadline nears

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-08 01:36:01 UTC
From: jghbeta
Topic: 7590 Message: 7590

I will be closing taking orders on Sunday, February 13.
Look for message 7575 "Board Group Buy" for details.
In addition to what is described there it will include a couple of additional boards. One of them has to do with something that Scotty and SamW have come up with. For now I'll say that it has to do with cleaning up the "zero response".
It is a great collection for the serious experimenter!

Jim W1JGH

Jim-

Count me in for one set. I didn't note how or when you want payment-any method is fine.

Hi Scotty - SA is now working with V116

It appears there was some compatibility issue with the MSA.Info file between the two versions. I did a quick cal with the V116 software running then tried it with V115(g) software and it worked ok.
But when I used the old MSA.Info file V115(g) worked ok but V116 would not - just the div by zero error.

Rex

7595. Re: MSA V116 and divide by zero error

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-08 14:31:16 UTC
From: Sam
Topic: 7573 Message: 7595

Rex,
The MSA_Info folder contains several files. The path calibration files are identical in the two versions, so you shouldn't have to replace those. There were some changes in the configuration and preference files, so the issue may be there. You might try running with the old MSA_Info, but with its preferences file (Prefs.txt) deleted. A new one will be created.

The other possibility is to run with the configuration file (config.txt) deleted. This will cause the Configuration Manager to run when you start up. You can then set the new configuration items (switches and video capacitors), and an up-to-date configuration file will be created. You'll also have to re-enter your RBW filter info and any other custom configuration info.

Sam W.

Rex,
I think I have an answer to your error. On my XP computer, Version 115 will open without ntport but will not be able to actually command the MSA Hardware. Version 116 will give a runtime error.
Even though you have the proper ntport files, they are not installed correctly. Do this:
After you have downloaded the "redist.zip" into the MSA folder, you must do the following:
1. Unzip it to create a folder called "redist"
2. Open the "redist" folder and find the file called NTPortDrvSetup.exe.
3. Double click it to run it. It will install the Ntport drivers into the correct system directories for your computer.
4. You may throw away the "redist.zip" folder and the "redist" folder. They are no longer needed (for that particular computer).

Scotty

Scotty,
Can you determine where the runtime error occurs by using the Debugger? Version 116, like 115, checks for ntport. If it is not present, no hardware operations should be attempted (unless via USB).

Hi Sam,
I'm fixin to take Dad out for supper and a movie. I'll search for it when I get back tonight.
I was using spectrumanalyzer.exe and spectrumanalyzer.tkn. I created the error when I deleted the ntport and zntport from the system 32 folder. 116 did not get to the first window before crashing. 115 opened but of course, no commanding, thus, blank main window.

Hi Sam,
Here is where the bug occurs:

```
        'Initialize latching switches. moved here by ver116-4b so cb is valid.
    if cb=2 then    'SLIM ver116-1b
        'An initial low on the PS bit that controls latched switches may be draining switch
capacitors
        'Set it high and allow some recharge time
        out port, 128 'For SLIM latch 4 to set PS high.(Sam, It hangs up on this line)
        out control, STRB 'latch 128 into SLIM latch 4
    end if
```

Debug say it can't find the module

7600. Re: MSA V116 and divide by zero error

Yahoo group: spectrumanalyzer (2011)

From: motorol9
Topic: 7573 Message: 7600

Hi Sam

Had to go back and recreate the files for V115 as I had deleted them.
It looks like it is the config file that caused the problem. If I left the V115 config file in the folder the div by 0 error came up when running V116. But if I deleted only the config file then ran V116 the config manager started and a new config file was created. There may be some compatibility issue with the additions that have been added to V116 config manager.

Thanks to you and Scotty for working this thru

Rex

>
> Rex,
> The MSA_Info folder contains several files. The path calibration files are identical in the two versions, so you shouldn't have to replace those. There were some changes in the configuration and preference files, so the issue may be there. You might try running with the old MSA_Info, but with its preferences file (Prefs.txt) deleted. A new one will be created.
>
> The other possibility is to run with the configuration file (config.txt) deleted. This will cause the Configuration Manager to run when you start up. You can then set the new configuration items (switches and video capacitors), and an up-to-date configuration file will be created. You'll also have to re-enter your RBW filter info and any other custom configuration info.

Jim,

Sorry to bother you, could you please send the attachment zip file to me, I tried several times but can't download it, and don't know why.

thanks!

Hi,

While we are on the subject, I found some minor flaws I think:

```
[DDS3Track]'ver111-39d
'This uses DDS3 as a Tracking Generator, but is limited to 0 to 32 MHz, when MasterClock is
64 MHz
'DDS3 spare output is rich in harmonics and aliases.
'Tracks the values in Working Window, Center Frequency and Sweep Width (already in the
command arrays)
'The Spectrum Analyzer function is not effected.
'PLO3, Normal Tracking Generator, and Phase portion of VNA will be non-functional
-
-
-
if cb = 0 then gosub [CommandDDS3OrigCB]'will command DDS 3, only
'delver113-4a if cb = 2 then gosub [CommandDDS3SlimCB]'will command DDS 3, only
if cb = 2 then gosub [CommandAllSlims]'will command all 4 modules. ver113-4a
if cb = 3 then gosub [CommandAllSlimsUSB]'will command all 4 modules. ver113-4a
'USB:01-08-2010
> if cb = 3 then gosub [CommandAllSlimsUSB]'will command all 4 modules. ver113-4a
'USB:01-08-2010
wait
```

This line seems to belong to the routine below?

```
[DDS1Sweep]'ver112-2c
'This forces the DDS 1 to the values in Working Window: Center Frequency and Sweep Width
(already in the command arrays)
'DDS1 spare output is rich in harmonics and aliases.
'PLO1, and thus, the Spectrum Analyzer will be non-functional in this mode.
'Signal Generator or Tracking Generator output will not be effected.
-
-
-
-
if cb = 0 then gosub [CommandDDS1OrigCB]'will command DDS 1, only
'delver113-4a if cb = 2 then gosub [CommandDDS1SlimCB]'will command DDS 1, only
if cb = 2 then gosub [CommandAllSlims]'will command all 4 modules. ver113-4a
>

wait
```

New scoop:

By artfully rearranging the individual PCBs and a little increase in board size I have been able to add the diplexer PCB (by popular demand) and the "zero response zapper" by Scotty/SamW. Here is what Sam says about it:

quote
Scotty pointed out that the "zero response" that actually extends up to 1 MHz or so in VNA modes, can be significantly reduced by adding a buffer amplifier in the path from PLO2 to Mixer 3. This prevents LO3 from leaking back into PLO2. Essentially, this requires 15 dB of attenuation, followed by 18 dB of gain from an ERA-33 or similar MMIC, followed by 3 dB attenuation on the output. I made up the attached layout for such an amp, which is about 1.2" x 0.9" and is designed to be placed "in-line", with its connectors sticking out each end. That way it can be placed in the cabling from PLO2 to Mixer 3. I haven't done the schematic yet, but it is similar to the MMIC amp on the Signal Router board--but that one was a little more complex because it was also designed to provide power for other boards. This one can be built as normal MMIC-plus-inductor (the inductor actually fits on the R6 pad), or it can be an inductorless buffer amp such as the one I use on my TG output.
unquote

I might add: If you use a male SMA in one end you could connect directly to MXR3.

There is a great deal of interest in this board. So, those of you still on the fence, don't miss out!

I think this has to do with the old config file not having info on the video filter capacitors, so they end up as zero. I think I have now fixed that.
Sam W.

Scotty,
Thanks for locating that. That initialization is supposed to be skipped if ntport is not present, so I have changed "If cb=2 then" to "If cb=2 and suppressHardware=0 then"

Sam W.

7606. Signal Interference

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-09 15:02:13 UTC
From: Sam
Topic: 7606 Message: 7606

I have posted a document on my web site that analyzes the significance of VNA measurement errors that can result from interference by signals of various strengths, compared to the signal of interest:

<http://www.wetterlin.org/sam/SA/Operation/Interference.pdf>

This interference can result from leakage in switching mechanisms, or any type of direct leakage from VNA output to input. It can also arise
from reflections that occur at VNA output or input. Even the effects of bridge directivity can be viewed as an interference issue.

I developed a table to show what the maximum errors are (for dB and phase) for an interfering signal that is a given level below the main signal, from -10 dB down to -60 dB.

At the end, I discuss the "VHF Transmission/Reflection Test Set", which is part of Jim's group buy PCB. It allows both transmission and reflection measurements at lower frequencies (to 100 MHz or 150 MHz) with a minimum of calibration and interference issues.

Sam W.

7607. Re: [spectrumanalyzer] Filter plus GROUP BUY. An update.

Hi Jim and All,
I would point out that the SLIM-IFA-33 is a specialized amplifier, but it is constructed on a general purpose printed wiring board called "PWB_RFA". You can build the 1024 MHz buffer amplifier on this pwb by replacing L1(L2) with a 68 nH or similar choke. Replace the filter circuit (C26,L27,C28) with an appropriate resistive pi type attenuator. You can add the 15 dB input attenuator (resistive pi type) to the pads at X21, X22 (R22), and X24.
 Also, this is a dual amplifier board and you need not populate the U2 side.
 I will update the web page for this pwb.
Scotty

New scoop:

By artfully rearranging the individual PCBs and a little increase in board size I have been able to add the diplexer PCB (by popular demand) and the "zero response zapper" by Scotty/SamW. Here is what Sam says about it:

quote

Scotty pointed out that the "zero response" that actually extends up to 1 MHz or so in VNA modes, can be significantly reduced by adding a buffer amplifier in the path from PLO2 to Mixer 3. This prevents LO3 from leaking back into PLO2. Essentially, this requires 15 dB of attenuation, followed by 18 dB of gain from an ERA-33 or similar MMIC, followed by 3 dB attenuation on the output. I made up the attached layout for such an amp, which is about 1.2" x 0.9" and is designed to be placed "in-line", with its connectors sticking out each end. That way it can be placed in the cabling from PLO2 to Mixer 3. I haven't done the schematic yet, but it is similar to the MMIC amp on the Signal Router board--but that one was a little more complex because it was also designed to provide power for other boards. This one can be built as normal MMIC-plus-inductor (the inductor actually fits on the R6 pad), or it can be an inductorless buffer amp such as the one I use on
my TG output.

unquote

I might add: If you use a male SMA in one end you could connect directly to MXR3.

There is a great deal of interest in this board. So, those of you still on the fence, don't miss out!

Jim,

Sorry to bother you, could you please send the attachment zip file to me, I tried several times but can't download it, and don't know why.

thanks!

Yes, the PWB_RFA will work well for the PLO2 buffer amp. The board that is included on Jim's PCB has only one amp stage and is slightly down-sized to 0.9"x1.2". It is designed to have connectors sticking out opposite ends, which might be more convenient if you don't want to actually mount it in the grid, but want to have it "float" in the cabling. But if someone has an extra PWB_RFA, there is no strong reason not to use it.

The other thing this board will accommodate is a 1206 resistor in place of the inductor. This lets you build a broadband amp that extends to fairly low frequencies, so long as you accept lower gain, which is perfect for something such as a TG buffer amplifier. That resistor can effectively become the first leg of an output attenuator, which can also give the output very good return loss. Likewise, an attenuator on the input can provide excellent input return loss. Altogether, it can provide good in/out return loss and reverse isolation, with just a few dB of gain, which is why I refer to it as a buffer amp.

The inductorless design does not work for the PLO2 buffer, because the minimum output attenuation is about 6 dB. So for that purpose the inductor would be used, which is fine because there is no need for broadband amplification. For that purpose the PWB_RFA board is just as good.

7610. Filter plus GROUP BUY

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-09 19:15:16 UTC
From: jghbeta
Topic: 7610 Message: 7610

Hi everyone,

A huge favor to ask:
I am being flooded with nice expressions of interest but at this time we are in Phase 2, which means receiving orders through PayPal. Phase 1 was to measure interest and see if the group buy would be justified and determine cost.
Email #7575 in the spectrumanalyzer yahoo site has the details on how to make payments.
Remember that the US Post Office does not insure overseas mailings, therefore the boards ship at you own risk.

Jim W1JGH

7611. SLIM Amplifier/Buffer

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-09 20:01:45 UTC
From: wsprowls
Topic: 7611 Message: 7611

Hi All,
I am in the process of releasing the "SLIM-RFA-1". It is specifically designed to be the Buffer/Isolator/Amplifier between PLO 2 and Mixer 3. This is for those wishing to decrease the "zero" interference.
I finished the web page dealing with the printed wiring board:
http://www.scottyspectrumanalyzer.com/pwb_rfa.html
This is the identical PWB that is used for the SLIM-IFA-33
I should have the web page for the SLIM-RFA-1 finished sometime today.
I would remind everyone, this module is not a "must" for the VNA, but it is an improvement.
Scotty

7612. Re: PDM testing using DDS1 and DDS3

David,
I'm sorry I didn't answer your question earlier. Had my head somewhere!
Yes, you can.
You can set up your VNA to sweep anywhere.
Halt the sweep.
Open Special Tests Window
Command DDS 1 to 10.70 MHz
Command DDS 3 to 10.700001 (1 Hz difference)
Connect each DDS output to the inputs of the PDM
In Main Window, click "Continue"
You should get a sawtooth on the Phase trace that transitions every 1 second. Play with the DDS 3 frequency for other rep rates.
Scotty

From: Sam
Topic: 7611 Message: 7613

Let me suggest another possibility as well. You can obtain isolation at the most critical frequencies--the vicinity of 1024 MHz--with an ferrite isolator. The isolation would not be as good as with the buffer amp, but it may be plenty. Isolators are also bigger than the buffer amp. But you don't have to provide power to the isolator. Besides, I've never used an isolator in an actual gadget, so it might be fun.

Here is a circulator for sale on eBay ($20+$10 shipping):

<http://cgi.ebay.com/Teledyne-Microwave-24022-Circulator-C-1S23T-9-/140282345859?pt=LH_DefaultDomain_0&hash=item20a97ab983>

The seller has a lot of them. An isolator, which is what we want, is just a circulator (which the eBay item is) with port 3 terminated in 50 ohms. You run the signal (LO2) from port 1 to port 2 with loss of a few tenths of a dB; any signal entering port 2 (which in our case would be the unwanted LO3) is supposed to get routed to the termination at port 3, with very little of it reaching port 1 (PLO2, which we are trying to protect from contamination).

As it happens, I have a Teledyne isolator with the same part number and appearance as this eBay Teledyne circulator, but my port 3 has a connector with built-in termination rather than an SMA connector. But I assume the matching part number means they are for the same frequency range. The eBay seller does not know the range of his (so they likely won't sell well), but mine is 950-1150 MHz. The isolation of mine is about 25 dB in a broad range around 1024 MHz and actually increases to 39 dB not too far inside the edges of the range.

There are also several other circulators or isolators listed expressly for the 950-1150 MHz range. E.g.:

<http://cgi.ebay.com/Teledyne-C-1S13T-3-Circulator-950-1150MHz-20dB-Isolat-/220609218325?pt=LH_DefaultDomain_0&hash=item335d558715>

This is another Teledyne circulator with the same part number but a totally different look. It is advertised as 950-1150 MHz with an isolation spec of 20 dB.

7615. Re: PDM testing using DDS1 and DDS3

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-09 23:18:37 UTC
From: davidhooau
Topic: 7582 Message: 7615

Hi Scotty,

Many thanks, this works well. I also connected the DDS 1 main output to the PDM ref, and the aux output to the LD input (and hence to the PDM input via the LD output) and got a nice picture of the DDS filter response.

Cheers,

davidh

From: wsprowls
Topic: 7616 Message: 7616

Hi All,
I have completed the Web Page for the Buffer Amplifier:
http://www.scottyspectrumanalyzer.com/slim_rfa_1.html
It can be used as the Buffer/Isolator between PLO 2 and Mixer 3. It is designed to have 0 dB gain, with about -38 dB of reverse isolation.
Scotty

7617. P+ Marker in 116

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-10 06:56:09 UTC
From: davidhooau
Topic: 7617 Message: 7617

Hi,

I'm not sure if I should post this here, or send a message to someone in particular about software problems.

In ver 116, placing a P+ marker in SA mode always places it at 0Hz. P-, L, R etc work fine.

Also, using the filter analysis function, when a peak is visible, causes the application to crash; let me know if the log needs to be sent to someone who cares. The message looks innocuous enough:

```
Please Note:
#handle
#special
These handles closed by Liberty BASIC.
Please add the appropriate CLOSE commands.
```

And the log starts with:

```
Runtime error: Bad command for #handle, COLOR

Error(Exception)>>defaultAction
Error(Exception)>>activateHandler: <anUndefinedObject>
Error(Exception)>>handle
Error(Exception)>>signal
Error class(Exception class)>>signal: <'Bad command for #han...'>
BasicRunProgram(Object)>>error: <'Bad command for #han...'>
```

Hi David,
 We (Sam and I) definitely care. Yes, this is a good forum to report software or hardware errors. This way, we can get to them quickly.
 The P markers and Filter analysis worked before, so it is probably a minor bug when transitioning the software to ver 116. Sam is working the filter analysis bug, but he may not have known about the P+ error.

The filter analysis is fixed, but I have not yet posted the fixed version. The P+ marker works for me. It automatically locates at the peak, so if your peak is at 0 Hz, it will go there no matter where you click.

From: davidhooau
Topic: 7617 Message: 7620

Hi Sam,

* With series crystal fixture between DDS1 and LD:
* Start MSA
* Halt
* Sweep, centre = 10.7MHz, OK
* Restart, Halt
* Special tests -> DDS1 sweep
* Continue (I have peak at 10.6985MHz -9dBm)
* Marker, P+, Double click on peak
* Marker text appears on screen at 0Hz -63.615dBm

If I place P+ prior to selecting DDS1 sweep, it is placed correctly.

The same sequence is fine with 115.

HTH,

davidh

Hi David,
 I think I can answer this one. I created the Special Test/DDS sweep with the intention of using only the Center Frequency and Span from the main window to control the DDS. All other functions that are in the Menu items were not expected to be used during this Special Test. Some may work, but it is purely accidental.

David,
I am not able to recreate that. Does your sweep actually include 0Hz, and the marker gets placed there, or does it get placed at some non-zero frequency but the text at the bottom shows it as 0 Hz?

Sam,

Here's another funny one. I'm using a 7.5khz rbw and if I set the span to 0.075 mhz I can step a marker only down with the "+ / -" buttons not up. At 0 Mhz I can move only up not down (?) When I change the span to any other value then 75khz all is well.

This part number has been discontinued from National Semiconductor.

There has been mention on this forum of a drop in replacement made by Analog Devices though the part number escapes me. I am sure someone
will pop up and give you the correct part number

Thanks Simon,

Did some more searching and found a ADF4113 in my stock. I now remember
that this part was recommended as a replacement some time ago.
This part seems to require a resistor of some value in pin 1 setting the
charge pump current value.
I remember some discussion about this several weeks ago.
The data sheets call the pin FLo or Rset. They might just have the same
function.
Need to study the specs a bit longer.

Jurgen

Correction.
I mean to say that the data sheets call pin 1 FLo or Rset. That seems to
be the only difference I can see.

7629. Marker stepping

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-11 00:22:30 UTC
From: Sam
Topic: 7573 Message: 7629

That is strange, but I think I found the problem. It has to do with the fact that frequencies are rounded to the nearest Hz. With small enough intervals between steps, this can cause some odd behavior if the interval is not an integral number of Hz. I think I fixed this particular problem, but other variations are possible with very small intervals between steps. For example, if you do a zero-width scan, you can place markers where you want by clicking, but if you try to move them with + or - they jump to the center. This is because they try to relocate based on their target frequency, and in a zero-width scan everything is at the same frequency.

Sam W.

Thanks Simon,

Did some more searching and found a ADF4113 in my stock. I now
remember that this part was recommended as a replacement some time
ago.

This part seems to require a resistor of some value in pin 1 setting
the charge pump current value.

I remember some discussion about this several weeks ago.

The data sheets call the pin FLo or Rset. They might just have the
same function.

Need to study the specs a bit longer.

Hello,

I would like to buy 3 x LMX2326.

So far I have been unable to find a source.

Is there a replacement part?

Thanks, Jurgen

Howdy Sam,

My sweep does not include 0Hz. The P+ marker doesn't appear on the screen at all.

As Scotty pointed out, it's fortuitous that the markers worked at all in version 115 for the test configuration I'm using, so please don't invest any effort at all in this matter.

Thanks.

7632. Re: Signal Interference

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-11 13:05:17 UTC
From: Sam
Topic: 7606 Message: 7632

I have updated the Interference document, so if you downloaded it you should grab the new one; same URL. I expanded it to cover stronger interference levels, such as interference which is as strong as the measurement itself. The new table, shows, for example, that a bridge with 36 dB directivity can be used without OSL calibration to verify whether return loss is better than 30 dB. If the return loss exceeds 30 dB you often don't care about its exact value. Thus, for many return loss and SWR measurements (which of course don't involve phase), you can use the SA+TG+bridge to measure what you want, without need for the full VNA features.

7633. 116 Beta

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-11 15:21:16 UTC
From: Sam
Topic: 7633 Message: 7633

I have posted an updated beta version of the version 116 software:

<http://groups.yahoo.com/group/spectrumanalyzer/files/MSA_version116_4f_Beta.zip>

This has a few bug fixes that have been mentioned. I also included .tkn and .exe files, and an S-Parameter file for a ceramic filter, which can be used for playing with the Two-Port module. Remember that you don't need hardware attached to run the software, so you can try filter matching with the Two-Port module even if your MSA is not finished.

Originally, the Two-Port module would allow certain actions, like filter matching, only if it had a full set of four S-parameters. Now, however, if you have a file with just S11 values, you can load it (after clearing any existing parameters) and a two-port device will be created from it. Your S11 will represent the input; the output is considered to be a shunt 50-ohm resistor, and the input and output are deemed connected by a huge resistor. In essence, this completely isolates the input and output, so nothing that happens at the output affects the input response, which makes it act pretty much as though the output were not there. That will let you see what the "matched" input S11 looks like if you add various matching components to the input.

If you use the .tkn and .exe files, you need to place them in your existing software folder so they have access to the various DLLs that are in that folder. If you have Liberty Basic, you should just run the .bas file. Doing so will require some initial compile time, but once the compile is done the program will run faster than using the .exe. And if you encounter an error, you will usually get more meaningful info about the error if you are actually running under LB.

If you are switching from version 115, you may have to toss your config.txt file before running, though I think I have fixed that problem. In any event, you should run the Configuration Manager to configure automatic switching, and values of your video capacitors.

I recently purchased a set of boards from someone off the list. I was told they were from a group buy from around May of 2010. I do not have any other details on the boards I have other that that. They all look to be the latest revisions though. While testing the control board I had a short on the 10 volt side of the regulator on the board. I traced the problem down to 3 via's in the 10 volt line to the ground plane. I simply drilled out the via's to remove thier connection I have included a photo of my board and the 3 via's. I searched the board and could not find a reference to this. I am posting this in the hopes that it saves someone else the frustration of tracking this down. If it was posted in the past please forgive the bandwidth.

Nice pictures. The boards look good. Those extra vias are odd, because they certainly aren't on Scotty's Rev C layout and I haven't heard of anyone redoing that layout--don't know why they would. My guess is that in the process of assembling the individual layouts into one big one, an accidental paste occurred that put those vias there. Anyway, once they are drilled out, no harm done.

Hi Dale,
 As Sam said, that is probably a combination of boards and whoever did it added the vias. It is certainly an error. It is highly likely you are not the only one with the problem. I suggest you take any other board you got from that group buy and inspect it against the released Express documentation from my Web pages. For example, that documentation can be found on:
http://scottyspectrumanalyzer.com/slim_cb_nv.html
 For that particular error, I would suggest the builder turn the board over to the ground side and "ream out" the ground plating in the via with a sharp drill bit. That way, you don't have to drill all the way through the board. This leaves the +10 v trace intact to handle the full current.
 By the way. I opened your attachment with Express without a problem.
Scotty

7640. DDS Rev D issue

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-12 03:36:40 UTC
From: radiotalk@xtra.co.nz
Topic: 7640 Message: 7640

Hi Scotty / Sam

Looking at the output J4 with a scope, DDS non-commanded, I have a 1380Hz 50% duty cycle 5v p-p waveform. I have removed C30 and U3 (7SZ04MX4) still self oscillates, removing C31 changes the freq to 17kHz or R10 stops the oscillation. It doesn't matter if J4 is terminated (via capacitor to 50 ohms) or o/c.

If commanded, a very short pulse width square wave appears at J2 & J3.

Is this meant to occur?

Regards

Chris

7641. Re: [spectrumanalyzer] DDS Rev D issue

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-12 04:34:46 UTC
From: william sprowls
Topic: 7640 Message: 7641

Hi Chris,
It possible for U3 to oscillate at this low frequency if there is no input signal to U3. This occurs when the DDS is either not commanded or if it is commanded to a frequency outside of the bandwidth of the DDS filter (10.7 MHz).
  For the MSA, the only time the DDS is commanded outside of its normal bandwidth is during "Special Testing" and its subsequent PLO doesn't care if it gets a "weird" oscillating signal.
  It is not possible for an oscillation to occur if U3 is removed.

Topic: 7640 Message: 7643

As Scotty said, oscillation of U3 is normal with no input coming through the 10.7 MHz filter. But once it is receiving a signal, the output should be a square wave with near 50% duty cycle, not a short pulse. Check the signal strength into and out of the filter. I don't recall what it should be, but I suspect the signal coming out of your filter is tiny, as in a few mV.

The nominal signal level out of the DDS crystal filter and into U3 should be about 1.2 v pk to pk., at 10.7 MHz.

As Scotty said, oscillation of U3 is normal with no input coming through the 10.7 MHz filter. But once it is receiving a signal, the output should be a square wave with near 50% duty cycle, not a short pulse. Check the signal strength into and out of the filter. I don't recall what it should be, but I suspect the signal coming out of your filter is tiny, as in a few mV.

I have removed C30 and U3 (7SZ04MX4) still self oscillates, removing C31 changes the freq to 17kHz or R10 stops the oscillation. It doesn't matter if J4 is terminated (via capacitor to 50 ohms) or o/c.

Hi Dale,

Sorry for your trouble and lost time. I'm glad you got it resolved. I don't think that board came from my batch. I did two group orders. The first one was for crystal filter switch boards only. They shipped out in the first two weeks of May 2010. The second group buy I organized was for Full panels and various individual boards. This group would have included the Control boards. They shipped out in the last 2 weeks of June and early July 2010. My boards have no silk screen or masking and are very light green in color. There was a group of boards that went out prior to my getting involved that had via problems on other boards (The PLO board, I think) They were Blue in color , I believe.

I have two Control Boards here from the batch that I sent out and they check fine.

I hope the tone of this e-mail doesn't sound defensive. It isn't intended that way, I just want to reassure the folks that ordered my boards that every seems OK with that batch.

Once again, sorry for your difficulties and lost time. Please don't hesitate to ask if I can be of further assistance.

Bob Fish

Hi Dale,

I just went to your excellent website and looked at the pictures (which I should have done before I responded). Those boards look exactly like the ones I sent out. Except mine didn't have those three extra vias on the 10 volt line (at least the two Control Boards I have here don't have them). So I'm not sure which group they were part of. Unless, there is a subset of mine that are screwed up. I sold 40 boards so there are plenty out there.

Let me know if you bought something from me that has mistakes and I will make it right.

Thanks,

Bob

Bob
Those boards are what I sold to Dale around Jan 5, 2011.
I did a complete check for all the boards today (compare the drill file and the via/hole pads on PC), these 3 extra vias are the only errors on control boards, the other boards have no similar error.
The reason I got these 3 extra vias on control board is that when I converted the drill file, I used a tool that allows me to put multi via at same time according to some generated guiding holes. I forgot disabling the multi via function before I put single via. Such a mistake should have been caught with a final check, unfortunately, for some reason, I did not do such a final check for that control board. I will fix those vias for the rest of control boards.
Thanks
Lin

Lin,
Does all this (drill files and such) mean that you have converted all the boards to the Gerber format? If so, some people might find the Gerbers very handy. Also, when you say you will fix the extra vias for the rest of the control boards, does this mean you have several sets of boards?

Sam
Yes. I used a different way to order these boards due to some misunderstanding at very beginning and I spent about 2 weeks to convert them to gerber and drill file.
Several reasons made me order more than one set of these PCBs. Yes, I have several sets at home.

Board is 39.25 for US, 45.25 overseas.

Scotty's amplifier uses the same board as the IF amplifier, only the components change. It is NOT included in this set. There is an amplifier by SamW with the same funcionality.

For the parts there is an estimate in Scotty's web page. I am NOT doing a group buy for parts.
The cost of the boards depends on the board dimensions and numberof buyers in a group buy.
It may run around 60-80 US $. If we can keep it simple, I MAY volunteer to organize a group buy for new comers.

A big variable in Scotty's cost estimate was whether or not you used SMA connectors or went the direct-soldered-coax route. That was in the days when SMA connectors were expensive. Now, the Chinese imports are so cheap that there is not much motivation to do direct soldering.

Another thought: In the Files section there are two files called SLIM-BOM_ALL, one in text form and one as a spreadsheet, which apparently can be uploaded to Digi-Key, which would then give you the cost. You would have to take out the Mini-Circuits parts, which are about $100. The files are from 2008, so there may be a few discrepancies from the current schematics, primarily because the LMX2326 is no longer available (use ADF4118 or ADF4113(the latter requires an extra resistor)) and the original diodes are no longer available, but this would give you a decent cost estimate.

And a suggestion on the resistors: You get a substantial price break on resistors at qty 50. I suggest getting all of them in qty 50. Each will come in a single strip in a labeled plastic wrap (sometimes the label is stapled to the bag so you have to manually peel-and-stick). Cut a slot in one end, slide the strip part way out and remove the resistors you want (just drop the resistors out; do not trim off the end of the strip). Then slide the strip back in. Store the entire collection in numerical order. This is how I keep my resistors and it makes them very handy to use.

For the most common capacitors, do a similar thing but order qty 100. They will come in a rolled strip in a labeled plastic bag. Cut a slot in the bag and let the end of the roll stick out. In this case, after removing a bunch of capacitors, you can cut off the empty part of the strip but always leave a small bit of the strip extending out the slot.

Hi Jurgen,

I was able to add the RFA-1 amplifier to the board.

Jim

Topic: 7654 Message: 7660

I loaded the BOM to Digi-Key and replaced all the obsolete parts. I also changed some resistors and capacitors to choose cheaper alternatives. Total price without SMA connectors or Mini-Circuits parts was $252. This does not include the video filter switch, RBW filter switch or the actual final filters. Those switches were added after the BOM was created, but they don't use especially expensive parts.

> Another thought: In the Files section there are two files called SLIM-BOM_ALL, one in text form and one as a spreadsheet, which apparently can be uploaded to Digi-Key, which would then give you the cost. You would have to take out the Mini-Circuits parts, which are about $100. The files are from 2008, so there may be a few discrepancies from the current schematics, primarily because the LMX2326 is no longer available (use ADF4118 or ADF4113(the latter requires an extra resistor)) and the original diodes are no longer available, but this would give you a decent cost estimate.
>
> And a suggestion on the resistors: You get a substantial price break on resistors at qty 50. I suggest getting all of them in qty 50. Each will come in a single strip in a labeled plastic wrap (sometimes the label is stapled to the bag so you have to manually peel-and-stick). Cut a slot in one end, slide the strip part way out and remove the resistors you want (just drop the resistors out; do not trim off the end of the strip). Then slide the strip back in. Store the entire collection in numerical order. This is how I keep my resistors and it makes them very handy to use.
>
> For the most common capacitors, do a similar thing but order qty 100. They will come in a rolled strip in a labeled plastic bag. Cut a slot in the bag and let the end of the roll stick out. In this case, after removing a bunch of capacitors, you can cut off the empty part of the strip but always leave a small bit of the strip extending out the slot.

Sam,

Could you put a spreadsheet of your Digi-Key BOM in the files section? I think Digi-Key makes it
easy to export one. It would be a big help.

Done:

http://groups.yahoo.com/group/spectrumanalyzer/files/MSA%20BOM/MSA_BOM_2_13_11.xls

I don't guarantee that nothing is left out, but using this should get you 99%-100% of what you need. To order from Digi-Key, you can create an order per the instructions in the file.

When I created the order, everything worked except the MMUN2211 transistor was out of stock. There are a bunch of MMUN22xx biased transistors, and I'm not sure it makes much difference which you use. I think MMUN2214 would be good, and it is in stock.

I substituted the AD9851 for the AD9850, the ADF4118 for the LMX2326, and the ZLLS400TA for the MBRX... diode. For the 10uF caps, I used only ceramic; one type (25V) for the spots that deal with the 20V supply (the voltage doubler and parts of PLO1 and 3), and a cheaper one for the lower voltage spots. If that's confusing, just order all of them as the 25V type.

A few other substitutions were made. Some were because non-ROHS parts are no longer available. There were dramatic price variations for capacitors, and I generally went for the cheapest as long as it was a quality type (NP0 for those up to 1nF; X5R or X7R above that) and a brand-name supplier (Murata, TDK, Panasonic, Yageo). The resistors are available from Stackpole for about 60% the cost of those from ROHM in the original BOM, but for some reason they struck me as suspicious so I stuck with the ROHM.

Enjoy.

Topic: 7654 Message: 7663

I also built a spread sheet that is broke down by module and has totals. I know the voltage regulators have the wrong count, I have not completed building yet so do not know how accurate the rest of it is. I put it on my web page, for those that are interested.

http://wentztech.com/radio/SpectrumAnalyser/SA.html

I have placed 3 orders with digikey for about $262.00. One of the orders has SMD solder and some other supplies on it. I have also spent about 100.00 on ebay for connectors, coax, etc, Plus the 100.00 from mini circuits, $60.00 for the boards. I think I now have all the parts needed to build my SA. That puts me at $522.00 So far. I would say that is a good number, not counting supplies for shielding, the cavity filters, and a case, all of which I already had on hand. I did have some of the Analog devices on hand like the DDS and Analog to digital converters.

I have also been collecting notes on the boards for the group buy that is going on if anyone is interested. Thought it would be easier if all the info was in one place, when I started using them.

7666. MMUN2211 substitute?

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-14 16:19:07 UTC
From: pzerkel
Topic: 7666 Message: 7666

Digikey is out of stock on the MMUN2211. Would the DDTC114ECA-FDICT-ND be an acceptable substitute?

Looks like the difference in specs is this part lists a frequency transition of 250MHz, but 2211 has no frequency listed.

Thanks

Thats what I orderd in place of the MMUN2211 for my build.

Dale

Topic: 7666 Message: 7668

Hi All,
In response to this substitution, I need to provide some information about the MMUN2211 device.
 It is used in the AtoD circuit output to drive the lines back to the computer. The AtoD chip can supply only 500 ua of current, not near enough to drive the computer, but more than enough to drive the MMUN2211.
  The MMUN2211 acts as an inverter buffer. By theory, there is very little delay from the input of the MMUN2211 to the output of the MMUN2211.
 But, here is what I found. When the AtoD sends a high level signal (+5v) to the input of the MMUN2211, the output of the MMUN2211 goes low (0v) within 50 nsec. This is proper and acknowledged by the people at ON Semi (Motorola).
   When the AtoD sends a low level signal (0v) to the input of the MMUN2211, it takes the output of the MMUN2211 to go high (5v) by more than 1.2 usec. This is 24 times the delay time acknowledged by the people at ON Semi (Motorola). Their support to me sucked.
 This test is repeatable in 4 devices by 3 builders. From an engineering view, this is usually a result of base current saturation in a transistor. However, the MMUN2211 has a 10 K series resistor and 10 K shunt resistor that should limit base current to less than 380 ua. We don't usually see this kind of problem with this low of a base current.
 The MMUN2214 has a 10 K series resistor and 47 K shunt resistor that should limit base current to less than 427 ua. This is a bit more than the MMUN2211 and this problem could possibly be worse when using the MMUN2214.
 I would ask anyone trying this device to make some timing tests once it is installed in the AtoD module. It is very possible that ON has mismarked the MMUN2211 device and that the MMUN2214 will work quite well.
 This problem didn't create any grief until David began integrating USB. His USB bus inputs are very fast and his system was "missing" pulses. He "fixed" the condition by slowing down the bus when taking serial data from the AtoD module. This allowed the MMUN2211 to "settle" before its output was read.

Thats what I orderd in place of the MMUN2211 for my build.

Looks like you need a push-pull output on that driver, instead of a OC.
The wire from A/D board to control board has inductance and capacitance, if the cap is driven by a 2.2k ohm from 5V, it might be slow charging, and create a slow rising edge. If a push-pull could be very fast (about 65 ohm or less, depends up on the driver capability of the IC).
Lin

From: nealmartini
Topic: 7569 Message: 7671

Scotty and Sam and All,

Unfortunately, I still haven't received a Liberty Basic Code Key or a CD. I sent an email to the support line but did not receive a response. Recall that I left three voicemail messages earlier and did not get a callback or response. Also, my credit card was immediately charged.

I tried to find a direct email for Carl Gundel (author of Liberty Basic), but was able to locate it. If anyone has his email address, please let me know.

I am continuing to post the status here so others might approach ordering their own Liberty Basic with some caution. Maybe the online link isn't the best way to go.

Any further suggestions are welcomed.

Neal

As I recall, the ADF has somewhat better specs. Maybe that is why the LMX2326 was discontinued.

7675. Phase noise pedestal

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-16 00:46:04 UTC
From: motorol9
Topic: 7675 Message: 7675

Hi

Have linked to 2 photo's to get comparisons to the phase noise pedestal I am seeing on the spec analyzer. Would be interested in comparisons to other spec analyzers to see if I have some additional problems.

Both screen shots are at 100Mhz using 300Khz and 1Mhz sweep width.

The signal source is a low noise HP signal generator.

Pic 1.

http://groups.yahoo.com/group/spectrumanalyzer/photos/album/773230570/pic/1281347871/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc

Pic 2.
http://groups.yahoo.com/group/spectrumanalyzer/photos/album/773230570/pic/42863583/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc

As a test I removed the 20 volt supply from the control board and used a Tektronix variable supply to run the 20 volt line. There was no difference in the data displayed so I think the 20 volt supply is clean (Cannot see any noticable ripple on a CRO)

Thanks

Rex

Order was placed with ExpressPCB and expect delivery on Feb 21. I'll be mailing within that week. The mailing boxes and bubbles are ready.

Attached is a pdf document with the final board layout and location guide. You will need the later to quickly identify the individual PCBs.

Hi Rex,
Both pics look outstanding. Just exactly what I would expect to see with a wide resolution filter such as your 18 KHz one.
 You didn't say that you had done Magnitude calibration. Either way, the phase noise ratio is within 2 dB of a theoretical.

All,

For those of you that have partaken in Jim's group buy of the filter plus boards.

I started collecting info on the boards included in the group by. Most notably documentation that Jim Provided, Scotty's and Sam's web sites, as well as postings on the list reflector. I thought that some of you might also be interested in the info so I decided to make it a web page instead of a word document for my note book!

It is located at http://wentztech.com/radio/SpectrumAnalyser/SA/FilterPlus.html

Dale,
 Just to prove I really do read everyone's web pages, yours states, plus a few other boards for use with the SMA.

I have designed the most expensive SMA in history! Hehe.
  I'm just poking some fun, as I have made this finger fumble hundreds of times.
Good page!
Scotty

Scotty,

Yes I have done that more than one time in the last few days :-)

I have to go to the store and get some more white out, I have gone through two bottles already this week, and the web page still is not done!

I just fixed it, but I am sure you will see it again on one of my pages, in the near future!

Folks,

Should one fit fences around the R port on mixers 3 and 4?

I experimented with fencing in Mixer 3 and could not detect any effect. That was a while ago. I don't recall the details but I recall concluding that to make the attenuation of the RF line fully effective, it might help to use a canned attenuator external to the mixer (never tried that, though). But I also have more than the normal attenuation, because I added an amplifier on the output, which provides a little gain but mainly improves the TG return loss and prevents high frequency reflections from the DUT back to Mixer 3.

Hi David,
 No, a waste of time. Fencing usually improves isolation, but the internal isolation of the mixer is the contributor, not the connectors. Just make sure the J1-J3 connections have their center conductosr clipped flush to the board, or as short as possible. This is just good general construction practice when working at UHF.

7687. ADC Testing Oddness

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-18 06:17:32 UTC
From: Dale
Topic: 7687 Message: 7687

I was testing my 16 bit ADC board. The mag side seems to react to the volt meter test quickly. When I test the Phase side it moves very very slow. I never let it get to 0 volts, I quit after about 15 min and it was still not there. I have tested everything even replaced the transistor. Ohms and voltage measurements seem good comparing the two. I originally had some parts that moved around on the board that I did not catch, and thought I damaged U3, but I replaced it. It is acting differently, by being very slow, but not the same as U2. I also noticed that the trace is not level when the switch is in the center position for the phase setting.

Anyone have anything that can point me in the correct direction?

Dale

7690. PLO3 tests in "test as you build"

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-19 09:37:04 UTC
From: davidhooau
Topic: 7690 Message: 7690

Oh Wise Ones,

I'm following the "test as you build" guide. All works fine for checking PLO2 and PLO1 (except my all mixers are missing about 2dB).

To get any sensible results for PLO3 I have to change mode to "SA with TG" and change the centre frequency to 10.7MHz to get any signal into the crystal filter. This matches my understanding of how things should work, as the TG output is the difference between PLO2 and PLO3.

Is this a documentation shortfall, or am I overlooking something obvious?

I'm using Ver 115, Rev G.

Thanks!

davidh

From: Dale
Topic: 7687 Message: 7691

Sam,

I went back and tested a bit more yesterday. I now have the phase ADC just about matching the Mag ADC. The difference I am seeing I think is due to the cap that goes from the input of the ADC to ground. They did not measure the same in circuit with my AADE cap meter. I also cleaned the board again real well and that seemed to help also. Even though my ohm meter showed close to the same reading when testing, I am guessing there was some gunk hidden under something that was causing the volt meter test that feeds a voltage to the ADC to be off. Once I cleaned everything the oddness with the switch in the center position went away also. If I short the Phase and Mag inputs together the numbers are almost identical, and they fall off at a very close rate now.

I assume the fact that you get a positive voltage reading that drops off, means the capacitor charges due to some board leakage (or IC leakage) and then discharges slowly through your voltmeter. If the capacitor itself has very low leakage, even a miniscule amount of leakage could charge it when there is no input attached. This might be another reason to attach a 10k resistor from input to ground before testing the voltage. This would more closely match how the input would function in the completed MSA.

Warning about some AD converters is that they may
draw significant input current during the conversion
process. This is the current that is used in the
charge balancing sequence and in general is solved
with low Z drive to the AD input.

I think you are right. The procedure states that PLO3 will automatically be commanded to 1034 MHz, which is where it would be with the default signal generator frequency of 10 MHz. But that frequency won't get through the filter. You don't have to change modes, you just have to set the SG frequency to 10.7 MHz. The SG is exactly the same as the TG, except SG is available in Spectrum Analyzer mode and stays at a fixed frequency, so once you set it to 10.7 MHz it doesn't matter what your scan settings are.

Thanks Sam,

I still don't get it. In SG mode, PLO2 is fixed at 1024MHz, PLO3 will now be fixed at 1034.7MHz, so the mixer output will be a constant 10.7MHz. This is now in the passband of the filter, but the display will be a horizontal line for all scan settings.

In order to "see" the crystal filter response, as per the previous steps, surely we need TG or VNA mode?

Hi Greg,
For many applications, your warning is quite valid. However, a low Z source to drive an A to D is only necessary when high conversion rates are taken. For the MSA, the conversion rate is less than 1000 samples per second (very low rate). The input capacitor (.001 uf) on each A to D satisfies as a low Z impedance.
This current draw by the AtoD only occurs for about 100 nsec.

Hi David,
 My "oops". The documentation is not correct. But you have already found the correct words I need to update the web page with.
"...change mode to "SA with TG" and change the center frequency to 10.7MHz."
  By the way, when testing PLO3, the mixing scheme changes to "low side mixing". The response of your Final Filter will reverse from what it looked like during PLO1 and PLO2 testing. If your filter is truly symmetrical (doubtful), you won't see a difference.

Correct. I was thinking in terms of verifying the output of the PLO at a specified frequency, not actually scanning with it. To scan, you need to use the TG and center the scan around 10.7 MHz.

7699. PLO1 and 3 frequency limited by 20V rail

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-20 09:15:04 UTC
From: davidhooau
Topic: 7699 Message: 7699

Folks,

Many thanks for all of the help and patience shown so far. I'm really enjoying building this gadget, and apologise for all of the list noise I'm creating.

Both of my PLLs were falling off a cliff at about the 1.85GHz mark, as the VCOs needed a higher voltage than the 18.6V available from the LT1677 with the 18.8V available from the CB. I've jumpered the voltage doubler to the input 12V rail, which just gets me to 2.1GHz. I don't really like this solution, as I'm relying on the LT1677 to function as a voltage regulator, so will find an alternative solution (maybe Sam's 23V regulator).

Is this a common problem? Should it get a mention in the SLIM or build doco somewhere?

Cheerio,

davidh

This isn't list noise; this is what this site is all about.

I haven't heard of this weak VCO problem before. Your frequency at 18.6V is well short of that in the "typical" chart in the specs. It sounds like even if you tweak the doubler voltage into the 19-20V range somehow, it would still not be enough. And I agree that directly using the 12V supply for the doubler does not seem like a good idea, though at least by that method you verified that the VCO can get to the necessary frequency. It sounds like you may need the +23V supply. Or, maybe you could use an 11V LDO regulator (if there is such a thing--maybe an adjustable regulator) to get regulated 11V to feed the doubler. (Actually, I don't know the doubler's max input voltage.)

Hi David,
 You should be getting 19.0 volts on the input to the PLO 1 (3) module. The LT1677 should see 18.94 volts. Make sure your 10 ohm voltage drop resistors are really 10 ohm. You have too much voltage drop.
 Do not use more than 10 volts for operating the LMC7660 doublers. I think 11 volts is absolute max for those chips.
Are you using other than the Minicircuits VCO's? Did you deviate from the specified components anywhere in the +20v circuits?
Scotty

Folks,

Many thanks for all of the help and patience shown so far. I'm really enjoying building this gadget, and apologise for all of the list noise I'm creating.

Both of my PLLs were falling off a cliff at about the 1.85GHz mark, as the VCOs needed a higher voltage than the 18.6V available from the LT1677 with the 18.8V available from the CB. I've jumpered the voltage doubler to the input 12V rail, which just gets me to 2.1GHz. I don't really like this solution, as I'm relying on the LT1677 to function as a voltage regulator, so will find an alternative solution (maybe Sam's 23V regulator).

Is this a common problem? Should it get a mention in the SLIM or build doco somewhere?

Cheerio,

davidh

Hi Scotty,

When the PLL is locked, the voltages are exactly as you say. When unlocked, one of the LT1677 input diodes is biased on, causing the additional current draw and hence the voltages I reported.

I think the VCOs are the likely culprits, as the control voltage @ 1013MHz is 3.27V (2.55V according to the guide).

I'm going to reconfigure in SG mode to check that the PLOs are generating likely correct frequencies, in case I have an issue with signal integrity with the digital control lines and am commanding the PLLs to stupid frequencies. I'll also try to borrow (or build) a decent counter, as my ancient fluke only goes to 125MHz.

Cheers,

davidh

Hi David and All,
 It is likely that your PLL's are locking to the correct frequency. You can be more certain when you have the basic SA chain completed.
 Of the Minicircuits VCO's I tested early in this project, all exceded the MSA frequency range requirements with the specified voltages created by the 20 volt doubler. PLO 1 would lock at 2013.3 MHz with about 17 volts on the Op Amp. It is quite possible that more recent batches of VCO's from MiniC are not as good.
 As Sam suggested, supplying 11.0 volts to the voltage doubler should solve your problem.

From: pzerkel
Topic: 7492 Message: 7704

I removed U3 completely, and replaced U2 and Q1 with new parts. Now when the ADC is powered up I get a trace at the TOP of the graph which does not move until power is removed (even as input voltage to J1 is varied). When the ADC has powered up, the input data is all 65535's. When power is removed the input data is all 0's.

I have checked voltage at U2-pin 3 and it follows the voltage input at J1.

I have two different control boards and the behavior is the same with this ADC attached to both control boards. Each of those CB's pass the test-as-you-build tests.

I do have an extra blank ADC-10 PWB and one extra AD7685 & MMUN2211, plus enough spare parts to build at least the MAG side of an additional ADC board. I will probably do that, and see if I can get a working ADC yet.

But still I would like to be able to troubleshoot this. It does seem to me that if the software is seeing 65536, then the ADC must be pumping out some kind of data?

I had exactly the same. Look at the serial out you might see only a single bit toggling, at least that is the way it worked for me. I needed to replace the chip and it now works fine. I must have damaged it by having reversed the DB25 connector.
Check for solder bridges.

From: Sam
Topic: 7492 Message: 7706

The software simply clocks the ADC to get it to spit out bits, and then reads. If the ADC is not working, the software will still read something. It reads the inverted value of SDO. So the fact that you read all ones doesn't mean the ADC is doing anything.

If the software is displaying the max ADC value (all ones), that means it is actually reading all zeroes from the hardware (due to the SDO inversion by Q1). That means the SDO pin is stuck high, or Q1's output is stuck low.

Either the ADC is not receiving the Convert or Clock signals, or it is not responding to them. Or, it is responding digitally but its conversion mechanism is messed up. Finally, maybe the SDO pin is responding but Q1's collector never goes high.

7707. Re: [spectrumanalyzer] Re: ADC trouble shooting

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-21 20:02:06 UTC
From: william sprowls
Topic: 7492 Message: 7707

Hi All,
 When testing the AtoD using the instructions on the web pages, there has been some confusion. With no input to the AtoD's the AtoD chips "see" only the video filter capacitors. During Wide or Mid selection, the input circuit impedance is extremely high. Basically, an open circuit input. The input voltage can "float" somewhere between 0v and 5v. This will give strange and irratic traces in both Mag and Phase. But, that is not a bad thing. If you see Magdata or Phadata moving around between 0 bits and 65535 bits, this is good. It means your pcb is nice and clean. You can read these bits by doing this:
a. Run the MSA software with the MSA hardware attached.
b. Halt and under menu item Options, select Show Variables.
c. "Continue" the sweep and read the Magdata and Phadata in the Variables Window.

 If you use a voltmeter probe from an AtoD input to ground, the input resistance of the voltmeter should pull the "floating" voltage to ground (or within a few millivolts to ground). The Magdata or Phadata should read 0 or maybe a few bits more.
 If you use the voltmeter probes from an AtoD input to +5v, the input resistance of the voltmeter should pull the "floating" voltage to +5v (or within a few millivolts below +5v). The Magdata or Phadata should read 65535 or maybe a few bits less.
  Now let me say this. Those readings will guarantee MSA accuracy. However, if those readings are off, do this:
Connect (or carefully touch) a 10K resistor from an AtoD input to ground. It must pull the "floating" voltage to ground. The Magdata or Phadata should read 0 bits. Connect (or carefully touch) a 10K resistor from an AtoD input to +5v. It must pull the "floating" voltage to +5v. The Magdata or Phadata should read 65535 bits.
 Your pcb may not be perfectly clean, but if these resistor tests are successful, your MSA will be accurate.

Here are a few more notes on the AtoD testing process.
1. The computer uses LPT, pin 11 to read the Magnitude AtoD.
2. The computer uses LPT, pin 10 to read the Phase AtoD.
3. Most computers have an internal resistor pull-up to its internal 5 volt bus. Usually the value is between 1000 and 3000 ohms. If your computer does not have pull-ups, they must be installed on the Control Board as R11 and R12. Here is a quick test to check your computer's LPT lines:
a. Run the MSA software without the MSA hardware attached.
b. Halt and under menu item Options, select Show Variables.
c. "Continue" the sweep and read the Magdata and Phadata in the Variables Window. They shoud both read 0.
d. On the computer's lpt port, short out pin 11 to ground (either the shield or pin 23 or pin 24). The Magdata should change to maximum count, 65535.
e. On the computer's lpt port, short out pin 10 to ground (either the shield or pin 22 or pin 23). The Phadata should change to maximum count, 65535.
f. If either fail to change, the computer does not have internal pull-up resistors.
g. For the computer to read a low level data signal (0 volts), the data source must "pull down" the computer. This requires about 2 ma of current. This is more than the .5 ma

allowable by the AtoD chip. This why the MMUN 2211 is used as a buffer between the AtoD chip and the computer. However, it does invert the data from the AtoD chip. The software knows this and accounts for it.
h. There is one problem that could create an error in readings. There is a time delay in the MMUN2211 in which an extremely fast computer could fail to read proper data. This "bug" has been fixed with a software change, but it is still possible. I am looking into a hardware modification to overcome this MMUN bug.
Scotty

I suggest installing the pull-ups whether your computer has them or not, because you may not always be using that computer.

I also suggest going directly to the 10 kohm test for the input because it sounds like not using the resistor is causing many false negatives due to very high impedance leakage paths.

Finally, when you test the phase ADC by connecting it to 0V or 5V through the resistor, the display will jump between 0 and +/-180 degrees because the software is trying to invert the PDM, which is not there. So you'll get the same jumpy display whether using 0 or +5V. 10k resistors to both 0 and +5V will give an intermediate value which should give a stable display at +/-180 degrees. (Conceivably, it could jump between +180 and -180 degrees, which is meaningless jump but messy on the screen. And strictly speaking with double resistors you should use 20k resistors to check for leakage to match the in-circuit impedance feeding the phase ADC.)

7709. PDM and Range Tests

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-22 22:51:47 UTC
From: davidhooau
Topic: 7709 Message: 7709

Folks,

I'm working on the PDM and Range tests, and have 2 queries please.

> In step 8, I'm seeing about 11dB "droop" from 0Hz to 1GHz, at both mixer outputs. I've posted an image in "davidh's build" in the photo section showing the mixer 4 output. All of the mixers do the same thing, using all PLO outputs in any combination. Is this normal?

> At step 11, when setting the span to 200MHz, I get a message "MESSAGE: PLL1, 2326 Bcounter<Acounter", and hence cannot check the PLO lower limits.

Thanks,

davidh

Sam makes a good point. If testing in the SA Mode, with the Vairables Window open, you will not get a Phase trace at all. You will, however, get the correct Phadata bit count.
 When in the VNA Mode and getting a Phase trace, you can open the Special Tests Window and select the PDM to go into the "Normal" configuration. This way, the trace will not toggle between the 0/180. Even better, change the left Phase scale to +360 degrees for the top and 0 degrees for the bottom. The trace will then not toggle between +180 and -180 degrees.

I suggest installing the pull-ups whether your computer has them or not, because you may not always be using that computer.

I also suggest going directly to the 10 kohm test for the input because it sounds like not using the resistor is causing many false negatives due to very high impedance leakage paths.

Finally, when you test the phase ADC by connecting it to 0V or 5V through the resistor, the display will jump between 0 and +/-180 degrees because the software is trying to invert the PDM, which is not there. So you'll get the same jumpy display whether using 0 or +5V. 10k resistors to both 0 and +5V will give an intermediate value which should give a stable display at +/-180 degrees. (Conceivably, it could jump between +180 and -180 degrees, which is meaningless jump but messy on the screen. And strictly speaking with double resistors you should use 20k resistors to check for leakage to match the in-circuit impedance feeding the phase ADC.)

From: Sam
Topic: 7709 Message: 7711

David,
Your graph runs to 1092 MHz with 11 dB droop. It looks like it would be about 9 dB to 1 GHz. Mine droops 8 dB. I thought of replacing the mixer until I found out another builder also had 8 dB droop. Yours appears to be in the same ballpark.

This is not a major problem, but it does create one issue. The PDM will function fine with this signal, except that the duty cycle of the input squarer will change very slightly over frequency. This means that the effect of inverting the PDM reference differs slightly over frequency. When you calibrate your PDM inversion, you may find that the phase shift caused by the inversion is, say, 190 degrees at 50 MHz and 190.5 degrees at 1 GHz. This means that if I specify the inversion as 190 degrees, an error of 0.5 dB can be created at 1 GHz when the PDM is inverted.

My PDM inversion is fairly constant to 200 MHz, and then starts to change slowly, with a max change of 0.5 deg.

I have not found this to be a significant problem, but I would like to eliminate the issue someday. One possibility would be a weak filter that would attenuate the lower frequencies perhaps 6 dB and not have much effect on the highest frequency. Maybe a simple filter placed together in series with the Mixer 4 RF input, would do the trick. Another approach would be to amplify the Mixer 4 output, because at higher signal levels the droop does not have much effect on the PDM. Finaly, the problem could be solved by having the software use a PDM inversion table at several frequencies, rather than a fixed value for all frequencies.

Some increased phase error at higher frequencies is acceptable because there are so many other error sources at those frequencies--such as the tightness of SMA connectors or minor defects in calibration standards. So I wouldn't sweat this issue until you have the MSA completed.

Hi David,
 I need to do some work on the Integration and Verification Test Procedure web page.
Step 11 is bogus. My fault. When PLO1 or PLO3 gets a command to go below a legal counter code, the MSA will give an error. For this step change the span to 20 Mhz. You should see a normal response with no break-up. This test is just supposed to verify the PLO's will operate at their lowest ratings.

Step 8 is another story. You really do have quite a drop off. However, you are starting with low power (-21 dBm). It should be around -11 dBm. Do you trust your attenuator? Also did you do the coarse Mag calibration earlier on the page.

I will look at this a little closer tomorrow.

I was focusing on the droop rather than the absolute level, so I didn't notice the low signal level that Scotty points out. You probably need to resolve that before worrying about the droop.

7714. Re: PDM and Range Tests

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-23 01:05:33 UTC
From: davidhooau
Topic: 7709 Message: 7714

Scotty and Sam,

Many thanks for your assistance. I'm relieved to hear that the droop isn't a show stopper (yet).

I've just checked the levels, and don't see a huge problem. All of my mixers measured around the 10dB loss mark (no I don't know why it's so high), so I have:

PLO (8dBM) -> MXR4 atten (14dB) -> ADE-11X (10dB) -> XF (4.6dB) = -20.6dBm

So I'm not too far out.

I did the initial LD/ADC cal using an HP3325A (which was last calibrated around the time of the French revolution) and will check it against Sam's leveler and an HP355D attenuator. The MFC has also changed since the initial test, so maybe I've bumped something in the process of putting the SLIMs into their little cases.

Nearly time to build the cavity filter!

Cheers,

davidh

7715. Taming the zero response

Yahoo group: spectrumanalyzer (2011)

From: Sam
Topic: 7715 Message: 7715

The zero response--the hump that appears around 0 Hz when there is no input signal--extends up to at least 1 MHz in VNA modes due to leakage of LO3 through Mixer 3 into LO2. The board Jim recently ordered has an isolation amplifier to insert in the line from LO2 to Mixer 3 to reduce that leakage. I got anxious to try this out, so instead of an amplifier I used an isolator (Teledyne, 950-1150 MHz, of which many are available on eBay). The isolator is a ferrite device that allows signal to pass from port 1 to port 2, but any signal entering port 2 gets routed to port 3, which in an isolator is terminated in 50 ohms. So it allows LO2 to get to Mixer 3 but does not allow LO3 to go in the reverse direction.

It works like a charm. My zero response in VNA modes now drops below -100 dBm at about 200 kHz. It used to take until 1 MHz to drop that low.

The isolator is a nice solution if you have the room (it's about 1.75" square), and doesn't require any power. The amp likely will provide better isolation, though this is pretty darn good (30 dB isolation).

US, Brazil & Australia boxes where mailed today Feb 23.
Canada, France, Germany, New Zealand, Sweden and the UK will be mailed tomorrow Feb 24.
That will complete the Group Buy. Over and out and enjoy.

5 are available. This is actually a circulator, so you have to add a 50-ohm termination to port 3 (which is shown in the photo but I don't know if it is part of the sale). It looks like it might be slightly bigger than mine.

I bought one of those and it came with the termination. It arrived, but I haven't tried to use it. Most of my electronic stuff has been moved to my new house, but I'm still at the old one and don't know when I'll get around to it.

Hi All,
 Just as small warning to those of us who have pacemakers. Isolators/Circulators have a powerful magnet inside. Although the case shields the magnetic field, it ain't perfect. Don't use one as a necklace.
 You can actually change its RF characteristics a little by adding another magnet on its outside. These things are "voodoo". Lotsa fun to play with.

Jim,

Received the MSA filter-plus PWB this week. Thanks for organizing the buy.

Did the two documents in your email below get revised when the diplexer
and zero response zapper were added to the board? If so, I evidently
missed them. Where could I find them?

Just trying to acquire the PWB documentation so I'll have it when I want
to use the board.

73,

Steve K8JQ

The diplexer documentation is in Sam Weterlin's web site.
The "zapper" is at Scotty's. I think he calls it the zero reponse buffer amplifier and it is the same boardas the IF amplifier but with different components.

7727. LO2 isolation amp and TG buffer amp

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-26 20:08:52 UTC
From: Sam
Topic: 7727 Message: 7727

Jim's filter board, which I just received (thanks, Jim) contains my isolation amp designed to insert between PLO2 and Mixer 3. I have also mentioned that I use an amp on the output of Mixer 3 (the TG) to improve the return loss and prevent a DUT from selectively re-reflecting high frequency signals (LO2 and LO3) back into the mixer.

Jim also included Scotty's amp board on this recent buy. Scotty has proposed using one side of that board for the LO2 isolation amp. It occurred to me that you could use Scotty's buffer amp board to get both amps on a single board. The catch is that the TG buffer amp must replace the MMIC inductor with a size 1206 resistor (or maybe two such resistors in parallel), but it appears that it will fit--perhaps sitting on its side.

Some isolation is necessary between the amps, but I think a shield down the middle would be adequate (even though it needs a hole in it for the power input). There is no fear of contamination of the TG signal by LO2--it already contains LO2. But we don't want PLO2 contaminated by LO3 (that's the whole point of the isolation amp). The LO3 level in the TG amp output will be maybe -20 dBm, and has to make it through the fence to the LO2 amp input in order to work its way back to PLO2 before it causes any trouble.

I posted a schematic and PCB for this combined amplifier (not yet built/tested), which I call the Mixer 3 Amps, in the Files section:

<http://groups.yahoo.com/group/spectrumanalyzer/files/Mixer3Amps.zip>

On the topic of the diplexer: It contains an attenuator that was intended to approximate in 2G the loss that occurs in 1G when the signal passes through the cavity filter and Mixer 2, which get bypassed by the 10.7 MHz signal in 2G. If you don't do that, it may be possible for the 2G signal to overload the IF amplifier.

I believe I originally counted on some attenuation occurring at the Mixer 1 output, where the 10.7 MHz signal has to pass through a small capacitor (100 pF I believe), so I made the resistive attenuator a bit smaller than it would otherwise have to be. Later on, I think I replaced the Mixer 1 output capacitor with a larger one, but never tweaked the diplexer attenuator. That was all long ago.

Bottom line, it's up to you to figure out the proper attenuation in the diplexer.

Hi All,
 As a note, I have revised the Block Diagram and Wiring Harness to include the optional Buffer/Amplifier between PLO 2 and Mixer 3. Although this addition will improve the isolation of PLO 2, it really is optional. Some builders may not be interested in the addition.
see:
http://www.scottyspectrumanalyzer.com/msaslim.html
This is the Web page for the Construction of the MSA. You may notice that I have deleted the two wiring diagrams for the Basic MSA and MSA with Tracking Generator. There are new notes on determining the requirements for wiring.

Jim's filter board, which I just received (thanks, Jim) contains my isolation amp designed to insert between PLO2 and Mixer 3. I have also mentioned that I use an amp on the output of Mixer 3 (the TG) to improve the return loss and prevent a DUT from selectively re-reflecting high frequency signals (LO2 and LO3) back into the mixer.

Jim also included Scotty's amp board on this recent buy. Scotty has proposed using one side of that board for the LO2 isolation amp. It occurred to me that you could use Scotty's buffer amp board to get both amps on a single board. The catch is that the TG buffer amp must replace the MMIC inductor with a size 1206 resistor (or maybe two such resistors in parallel), but it appears that it will fit--perhaps sitting on its side.

Some isolation is necessary between the amps, but I think a shield down the middle would be adequate (even though it needs a hole in it for the power input). There is no fear of contamination of the TG signal by LO2--it already contains LO2. But we don't want PLO2 contaminated by LO3 (that's the whole point of the isolation amp). The LO3 level in the TG amp output will be maybe -20 dBm, and has to make it through the fence to the LO2 amp input in order to work its way back to PLO2 before it causes any trouble.

I posted a schematic and PCB for this combined amplifier (not yet built/tested), which I call the Mixer 3 Amps, in the Files section:

<http://groups.yahoo.com/group/spectrumanalyzer/files/Mixer3Amps.zip>

That file allows simulation of a 5-xtal filter, with different crystal parameters for each. It's a bit of a pain to enter the values (RFSim99 only allows so many significant digits; to get more you have to use two series inductors or two parallel capacitors, one big and one small), but once you have the data entered you can play with it as much as you want. That lets you see how well a particular set of filters (which you test with Crystal Analysis) will actually perform in a circuit that was designed using a single set of specs for all crystals. It also lets you tinker with the coupling components. Each crystal (except one, I think) has a series capacitor used to tweak its frequency (lower capacitance raises the frequency), so if you have a crystal for which you know the frequency is low, you can try lowering the series capacitance.

It is absolutely true that these amps are optional. You don't need to even think about them until your MSA is up and running, other than perhaps reserving space for them. I think the isolation amplifier is a great idea, but I've been operating the MSA just fine for a couple of years without one.

7733. LD coarse cal (test as you build)

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-27 09:07:57 UTC
From: davidhooau
Topic: 7733 Message: 7733

Folks,

There's part of the LD coarse cal which I either don't understand (or disagree with).

Looking at the AD8306 data-sheet, in particular figures 8 and 11 on page 5, shows the 10MHz response falling away at about -90dBV (about -102dBm at the transformer input). This matches the tests I've done, where I'm seeing the gain start to flatten out at around -90dBm and pretty much fall off the cliff at -100dBm.

The TAYB procedure sets up a path 1 cal file using the "loaded" log detector noise floor and sets this ADC value to -116dBm. This is the almost same ADC value I'm seeing for -100dBm signals, and as a consequence, there's a considerable slope error between the -8dBm point from DDS1 J3 down to this basement level.

When I re-cal using an additional point below the level expected during the mixer tests, I have found most of the mysterious 2dB of mixer loss from previous tests has been rediscovered (sadly not all of it yet).

Have I missed something obvious? Or, is it worthwhile changing the TAYB to ask for an additional measurement using an attenuator, or should the current -116dBm value be changed to something around the -100dBm mark?

Thanks,

davidh

I'll leave the -116/-100 dBm issue for Scotty, but I'll address a related issue.

Since the bottom calibration point is at or near the noise floor, the true graph of dBm (y axis) vs ADC (x axis) will be very steep at the low end and then reach a stable slope on its way to the -8 dBm cal point. But the software will use a fairly straight line between the two points (not quite straight, because cubic interpolation is used). The line used by the software is thus below the true line, and dBm values below -8 dBm are under-estimated.

An extra calibration point would improve the results, but I believe Scotty was trying to get a coarse calibration that did not depend on using a signal generator. The results using coarse calibration between -8 dBm and +11 dBm should be pretty good.

Hi David,
 You bring up a good concern. What would be best is supply the MSA software with some pre-loaded values that conform to a completed log detector module. I would also like the same type of data for a completed MSA (front end input vs Magnitude bit count). We "sorta" have the latter in the Path 1 pre-loaded table. But it is too coarse. I will perform a calibration of the Log Detector and create a table and use it for a pre-load for Path 2. This will help builders who are testing as they build.
  If you (or anyone) would like to, perform a Mag Cal on your Log Detector and send me the results to compare to what I get. Use 10.7 MHz +/- 1 MHz. Go from +15 dBm (or as high as you can) to -110 dBm in 5 dB or 10 dB steps (or finer steps if convenient to you). Your table will be LD input power (in dBm) vs. Magnitude bit count. Of course, the Magdata is available in the Variables Window.

Scotty,
Good idea to create a standard table, but I don't think it requires a whole lot of points, since the log detector specs allow +/-2.5% variation in slope (mV/dB) and +/-1.5% in intercept, so there will be errors anyway.

I'm also curious about the -116 dBm noise floor level. Sounds like David would have pegged the noise floor at -100 dBm. Below -100 dBm are getting ADC changes on the order of 1 bit per dB?

Howdy Scotty,

Below is the table generated using an un-cal'd 3325A as a signal source and 355D switched attenuator. My ADC reference is 4.9751V.

I have to travel for the next week, but will repeat the tests on my return, as my LD appears to be outside the data-sheet specs (from 0 to -10dBm I see 211mV/10dB).

Many thanks.

davidh

From: Greg Broburg
Topic: 7715 Message: 7738

The magnetically activated reed switch in the pacer is
intended to force the pulse output into the uninhibited
program rate. It's intended for a physician to be able
to observe the programmed pacing interval if there is
enough normal activity to inhibit. Most patients pacers
are inhibited a lot, waiting for a missing beat. Also,
there may be a programmed rate change for low battery.

You gotta get awfully close and in the correct field
orientation with the magnet from the pacer can in order
to activate the switch.

Hi David,
 After comparing your Log Detector data to the Verification MSA's Log Detector:
1. Your slope between linear points (+10 dBm to -80 dBm) averages 20.67 mv/dB. My slope is 20.55 mv/db. This is only a difference error of 0.6%. With these two data sets, one can use an average slope (among various Log Detectors) of 20.61 mv/dB. The slope of the Log Det is slightly affected by Vcc.
2. With the 16 bit AtoD, this is an average slope of 270.1 bits/dB.
3. Your data at 0 dBm is 1.1 dB different than the Verif MSA. However, you stated your 3325 is uncalibrated, and my source was calibrated. So, one can assume that 0 dBm into a Log Detector should produce an output voltage of 2.16 volts, with a bit count of 28326. Using that value as a calibration point, there will be some error from unit to unit because the voltage output of the Log Det is also slightly affected by Vcc.
4. Your data point at +11 dBm looks bogus. I'll bet my paycheck (well, I don't get one anyway) that your data point is really +15 dBm or higher.

Bottom line to all this. If any builder would like a "pre-set" coarse calibration for the Log Detector and 16 Bit serial AtoD, do this:
1. If you don't have a path 2 filter, create one in the Hardware Configuration Manager using the same filter characteristics as the one in Path 1. If you do have a real filter to use in Path 2, you can use Path 3 or Path 4.
2. Open the Initial Cal Manager, and click the path 2 (or the path you want to use). This changes the table to Path Calibration Table.
3. Enter 3 sets of values:
ADC = 0, dbm = -104.91, Phase = 0
ADC = 28326, dbm = 0, Phase = 0
ADC = 65534, dbm = 137.81, Phase = 0
delete any other sets of values
4. Click Cleanup, then click Save File
 (Of course, the -104 and 137 dB points are not obtainable, but the values establish data points for the software to calculate "real" power inputs.)
5. From this point on, you can command the MSA to use Path 2 and the Magnitude will indicate the exact power on the input to the Log Detector, NOT the power input to the MSA. It should be fairly accurate (+/- .5dB) from +15 dB down to -80 dBm. Below -80, the Log Detector is operating in its non-linear area, but it will certainly indicate data. Due to some error from MSA to MSA ,your mileage may vary!

Howdy Scotty,

Below is the table generated using an un-cal'd 3325A as a signal source and 355D switched attenuator. My ADC reference is 4.9751V.

I have to travel for the next week, but will repeat the tests on my return, as my LD appears to be outside the data-sheet specs (from 0 to -10dBm I see 211mV/10dB).

Many thanks.

davidh

7740. Mixer 3 Amps

Yahoo group: spectrumanalyzer (2011)
Date: 2011-02-28 20:41:27 UTC
From: Sam
Topic: 7740 Message: 7740

I have built the "Mixer 3 Amps"--an LO2 isolation amp and an amp for the TG output. They are together on Scotty's IF amp PCB--the one included on Jim's board. Results are good. Both of them amplify properly. The LO2 isolation amp has a net gain of 0.5 dB (with 10 dBm input), and the TG amp has a net gain of 3 dB (with -10 dBm input). (The amps are mainly for isolation, not gain). I might reduce the input attenuator on the TG amp a bit.

I have no fencing whatsoever, and the isolation between the input of one amp and the output of the other is better than 70 dB at 1 GHz! (Good layout, Scotty.) I have not yet installed them in the MSA; I just tested them on the bench.

To make the 120 ohm resistor for the TG amp MMIC output, I used a size 1206, 220 ohm resistor installed in the normal manner, and a size 1206, 270 ohm resistor lying on its side next to the first one. There was plenty of room for this. I did it this way to improve heat dissipation over what it would be with the resistors stacked, or with a single 120 ohm resistor. In theory, a single size 1206, 120 ohm resistor could handle the heat (0.16 Watts), but I like to keep temperatures low. You probably could use some combination of side-by-side 0805 resistors, because there is plenty of room.

Sam W.

A little more info. The reverse isolation of the LO2 amp at 1 GHz is 40 dB. That's almost exactly what one would predict from the 16.5 dB attenuation plus 22 dB reverse isolation of the ERA-33SM. That means it will reduce by 40 dB the leakage of LO3 into LO2. I believe that is far more than I actually need.

A major purpose of the TG amp is to get good output return loss. Up to 150 MHz, the return loss is better than 40 dB (near 50 dB at some points), which is excellent. It declines to 20 dB at 1 GHz. It's a bit of a mystery to me why it declines that far, but 20 dB is still decent.

7742. 11.155MHz crystals available in the UK

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-01 20:19:34 UTC
From: g3wie
Topic: 7742 Message: 7742

Hi All,

Recently I purchased about 80 pieces of 11.155MHz crystals via the UK fleabay. I got them for a song as no-one else was bidding, with the thought they may well be selectable for use in the ladder filters of recent fame on this list and as featured in a group buy pcb.

I'd like to make them available at zero cost apart from postage, in the same spirit as the previous huge batch which Scotty and Sam so valiantly tested (and of which I have some sets for my ssa). However they will require matching, and my ssa/vna is still in kit form. It's pretty much next on the project list and matching up a sets of crystals would be a good first use for it, as well as training for the operator. However, that will take some while to happen (realistically Christmas 2011). If anyone else would like to take up the challenge on a faster timescale, I'll happily ship the crystals along

Nice offer. I can't take any credit for the previous testing of the 10.11 MHz crystals. That was Scotty and Jerry Barnett. Jerry actually provided the crystals.

Hi Chris,

It takes a LOT of crystals to be able to match them closely. Scotty went through about 1000 crystals, and I went through about 2000, from a really good buy on Ebay . These are 10.111 MHz crystals. I still have several thousand left, unsorted, if anyone else wishes to tackle the job. The bigger the tested batch, the higher percentage yield of good matches. You might not get that many close sets from 80 crystals.

Hi Lin,
 Be sure to factor in the insertion loss of each filter. Perhaps the 7.5 KHz filter has more loss. A better reference to each other will be accurate once you have calibrated.

Hi Lin,
I'm not sure of your question. The Rev E panel is one big panel. If you want to create a larger panel with other modules and include the Rev E panel, do this:
Open the Express .pcb of the PWB you want to include. "Copy" the whole pwb. Open the Express .pcb of the Rev E from the same application. "Paste" the pwb anywhere near, but not on top of what is already there. While it is highlighted, do a "Group". Then move it where you really want it. "Save" with a new name.
 To add another pwb, open it from the Rev E application and repeat the process.
You can move any of the pwb's around, but I caution you to make sure it is "Grouped". Otherwise, you may leave parts of it behind.
 Also, you should remove any text that refers to the new panel as Rev E. Give it a different name, such as "Lin-03-02-2011".
Scotty

Lin,
If you are making a big panel you may also be thinking of getting solder mask/silkscreen. I don't know whether the Rev E panel was designed for that, so you may have to make changes. You need to block solder mask on the entire bottom. You also need to block it on the top around the perimeter of each board. If the perimeter ground plane is made with rectangles or filled plane, it will have solder mask. To block it, you need to use "pads" or explicitly use solder mask stop. Finally, the solder mask stop layers display separately from the trace layers, so if you select and copy or select and move, you can't copy/move everything at once, which is a bit awkward.

7749. Re: 11.155MHz crystals available in the UK

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-02 15:28:53 UTC
From: Sam
Topic: 7742 Message: 7749

Good point. I went through about 50 crystals to get two sets of 5. But help may be on the way. One purpose of the 4-crystal buffered filter that was included on Jim's recent board is to simplify the matching requirement. I probably won't be able to try this out for a while, but I hope someone will.

The board has two pairs of crystals joined through a buffer amplifier. Each pair should be easy to tune because each crystal will be responsible for a peak in the response and you just need to merge the peaks together. The Rm of the crystals is almost irrelevant (but stick with <=20 ohms if you can) as the amplifier can offset the loss, which is likely to be small anyway.

Frequency matching is also not critical, as long as you know the relative frequencies and their very approximate Cm values. Say you have four crystals that deviate from the target by 0, -100, -200 and -300 Hz. (You actually select the highest frequency as the target, so you will always have deviations of zero or negative values.) You make the first pair out of the 0 and -100 crystals. The 0 does not need a series capacitor; the -100 needs one to raise its frequency. The other pair consists of the -200 and -300, both with series capacitors to raise their frequencies to match the 0 crystal. (Actually, it doesn't matter which is paired with which, as long as you keep track.)

To get an idea of what series capacitance you need, you can use the fact that if the crystal frequency is P percent too low, where P is relatively small (it will be less than 0.1%), the internal Cm of the crystal needs to be decreased by 2P percent. This requires a series capacitor that is Cm/(2p), where p is P expressed as a ratio (p=P/100). If you don't know Cm, use Cm=0.018 pF as a starter.

The pairs can be tuned individually, since they have no resonant interaction. Just put a jumper across the pair you are not tuning. (And across its impedance matching components to the input or output.)

There are also coupling capacitors that can be adjusted, but based on simulations, the default values are likely to work well.

As I said, I have not yet tried this, but I don't see why it would not work with crystals that are off by 1000 Hz or even more.

On the other hand, if your crystals are close in frequency (maybe max deviation of 50 Hz?), this filter may work with no series capacitors at all--i.e., no tuning.

This 4-crystal filter is intended for very narrow bandwidths, and you don't have much choice of bandwidth. Based on simulations, it is likely to be in the 300-800 Hz range. And four crystals are plenty to get good ultimate attenuation in a narrow filter.

I did the above-mentioned simulations with data from a set of my crystals and a set of Scotty's. My Lm and Cm values differed by a factor of two from Scotty's, but the default circuit worked well with both.

Sam W.

7750. LPF on TG

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-02 18:44:00 UTC
From: Sam
Topic: 7750 Message: 7750

In the process of installing the new Mixer 3 amps, I have been playing with the TG output, which at the moment comes directly from mixer 3 with no buffer amp. I checked the output level at 100 MHz (running it to an HP analyzer), then inserted a 700 MHz low pass filter and checked again. The output level dropped 1.3 dB. So the filter must have 1.3 dB insertion loss, right?

Wrong. The actual insertion loss is 0.2 dB. The remaining loss comes from the filter reflecting LO2 and LO3 components back into the mixer. (Or, you could look at it as the filter shorting those components to ground). Due to phasing, the reflected components reduce the mixer output of 100 MHz by 1.1 dB; with a different reflection phase they might increase the output, and the effect might even be more than 1.1 dB.

Suppose you had two DUTs, one a 700 MHz low pass filter and one a 700 MHz high pass filter, both with insertion loss of 0.2 dB at 100 MHz. If you attach the low pass filter you get 0.2 dB of true insertion loss plus the bogus 1.1 dB decrease in output. If instead you attach the high pass filter, you get the correct 0.2 insertion loss, because the high frequency components are largely unaffected.

The point is that the measurement of a DUT at low frequency will be affected by its performance at high frequency, which is very undesirable. A side-benefit of the TG amp is that it isolates the output and prevents these reflections from having any significant effect. But an alternative is simply to leave a low-pass filter in place for all measurements, which is workable as long as you are not concerned with frequencies above the passband. The low pass filter has the advantage of also reducing any stray 1013.3 signal and also reducing 3G components that might be interpreted as 1G. Finally, the filter reduces the LO3 component, which causes a 10.7 MHz spur.

I use a MiniCircuits LFCN-575D low pass filter, which really kicks in at around 700 MHz. It is similar to a large SMT ceramic capacitor, but has its ground terminal on the bottom, extending up the sides. You build the board with connectors sticking out the ends like an attenuator. Multiple copies of the tiny board have been included in several of the recent PCB buys. (I think it is marked "LFCN".) I frequently use one on the TG and one on the MSA input. I suspect that some people who bought those boards have extras, so if anyone is interested in one you could post an inquiry here.

7751. Cutting apart circuit board panels

Yahoo group: spectrumanalyzer (2011)

From: undercoupled
Topic: 7751 Message: 7751

Has anyone tried using a scroll saw with a fine pitch blade to separate the boards on a composite board panel? I don't have access to one to try. Probably prudent to try some scrap pcb first.
I have a large shear, but using it to shear small boards is like trying to kill a mosquito with a sledge hammer.

Yes, I tried it, two problems the blade has too much flex and it wore
out before I got one board free.

I always use a proxxon scroll saw with 36 tpi and other than poor blade life it works nicely

I haven't used them, but there are some carbide coated scroll saw blades available. Not inexpensive though at about $6.00 US each. Breakage before they get dull would be a concern for me at that price since I seem to break them through poor technique. It might cost less overall to use the cheaper blades.

Hi Guys,

I've cut alot of boards up in the last few months. I started by using a hack saw blade, but before long, I realized that it took way too long and it was way too hard to be accurate. The cut would wander one way or the other and It didn't take long before you were dangerously close to the copper. I tried a jig saw, a scroll saw and a dremel tool with a cutting wheel attached. The scroll saw was probably the best of this bunch, but still not great results. The way I ended up cutting 99% of the boards I prepared for shipment
was as follows:

I placed a the panel of boards on my work bench. I then clamped a metal straight edge along the intended cut line and C-clamped the straight edge in place on top of the boards and to the bench. I then scored the boards along the straight edge 6 or 7 times with a very sharp (brand new blade) utility knife. I then turn the panel over and do the same thing on the other side of the board on the same cut line. A word of caution here, make sure you use a THICK straight edge, (I used the ruler part out of my combination square) at least 1/16th inch thick. You don't want that knife blade to jump up over the straight edge and take off a couple of fingertips. Another tip, center the knife blade between the copper traces of adjacent boards first, then slide the straight edge against the knife blade, then clamp it. If you center the straight edge first, your cut will not be centered. It will be offset by the thickness of the cut (it will be slightly wider than the blade because of the fibrous nature of the material). Trust me, it makes a difference on some of the cuts that have adjacent boards very close together. After the board is scored 6 or 7 times top and bottom along the cut line. I placed it in my Super Duper Harbor Freight bending brake, clamped it along the cut line, lifted the handles and it snaps the board right along the cut line. A couple of passes with some coarse sand paper (for flatness, place the sand paper on the bench top and draw the board across it) and your good to go.

If you don't have a bending brake, you could probably get away with clamping the board to the bench top under a piece of plywood or something and lifting with your thumbs. I didn't try this, but I suspect it would be OK. A bending Brake is perfect because it focuses all the force on the cut line.

Here is the exact brake I bought, I originally bought it to make electronic enclosures out of sheet aluminum, but I haven't made any yet. I've sure cut up alot of boards with it though.

http://www.harborfreight.com/30-inch-bending-brake-67240.html

The best part of this method is very little dust. All the saws and the dremel tool method produced dust clouds. Breathing fiberglass dust is not good for you. I kept a shop vac with a HEPA filter handy for clean up because of the large number of boards I cut.
Fiberglass dulls knife blades very quickly. It may take you several to do one set of boards.

Sorry for the long post but I thought some one might find it helpful. Of course, use this method at your own risk. That utility knife can do alot of damage if your not extremely carefull!

7757. LO2 Isolation Amp installed

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-02 23:45:20 UTC
From: Sam
Topic: 7757 Message: 7757

I have installed the LO2 isolation amp in the line from PLO2 to Mixer 3 to prevent leakage of LO3 into PLO2. The results are impressive and are shown in my album:

http://groups.yahoo.com/group/spectrumanalyzer/photos/album/252922278/pic/list

There are two photos of the Zero-Response, one with and one without the buffer amp. At 100 kHz the level dropped from -75 dBm down to -95 dBm, and by 500 kHz it is into the -120 dBm noise floor. This greatly expands the dynamic range of the MSA at low frequencies, especially below 1 MHz. This is especially nice for the Component Meter function, which prefers to measure large capacitors at 100 kHz. I haven't tested it, but this expanded range conceivably could increase the maximum measurable capacitance by a factor of 10.

The zero response is in the noise by 500 kHz, but it is still there. There is a trick that can be used to detect it, as I showed in a document I posted somewhere, but can't remember where. If you do a zero-width Transmission mode scan at 1 MHz, with a 50-ohm termination on the TG and the MSA input connected to a 1 MHz signal source, you would expect to get a straight line graph. However, the phase of the signal source will drift with respect to that of the zero response, and the result will be a sine wave, if the zero response is strong enough to show itself.

At 1 MHz, with a -100 dBm input signal, I got a sine wave with amplitude about 1 dB, meaning the zero response was causing +/- 0.5 dB of error. Based on the table in my "Effects of Interference" paper, this suggests the zero response was about 26 dB below the input signal, or -126 dBm.

At 2 MHz, the zero response was just barely detectable as a wavy line with input of -105 dBm, suggesting it was below -140 dBm. This is important because 2 MHz is a nice frequency to use for path calibration. I previously suggested shifting to 5 MHz for low level calibration, but that is not necessary with the LO2 isolation amp.

7758. TG Amp

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-03 00:48:28 UTC
From: Sam
Topic: 7758 Message: 7758

First of all, my last post stated that the LO2 Isolation Amp is impressive. I'm not tooting my own horn here; it was Scotty's idea. Great idea.

Second, the LO2 amp is built on the IF2 amp board which has room for a second amp. That's where I put the amp for the tracking generator. If you're going to do the LO2 amp, there is really no reason not to do the TG amp as well.

Benefits of the TG amp:

1. Higher output level, if you choose. For VNA modes, the MSA can accurately take inputs somewhere in the -5 dBm to 0 dBm range. When you feed a bridge in Reflection mode, the max output of the bridge may be anywhere from 6 to 20 dB below the input signal, so even a 0 dBm TG output could be useful.

2. Excellent output return loss for at least a few hundred MHz. This greatly simplifies many measurements. OK, so you could accuse me of being a member of the return loss police. Guilty.

3. Suppression of reflections of very high frequency signals back into Mixer 2. Discussed in recent postings.

Thanks!

I wasn't excited about spending a minimum of $50 at minicircuits for a $10 part.

I'm looking at the coilcraft part: WBC16-1TL_

on the table here: http://www.coilcraft.com/wbc.cfm#table

Is that an equivalent part? It seems like it:

It's 1:16 impedance ratio, surface mount, and .6-300 Mhz bandwidth.
Also, the minicircuits is .17" by .17" where the coilcraft is .15" sq.

Scotty
When I reviewed my question (that I wrote at midnight) today, it is very confusing. Here was the reason I ask that question:
I tried to merge/update some collection boards, like cal source, leveler..., but I got some problems. Therefore, I looked at your Panel Rev E, I found you grouped the modules, and I could not know how to group my modules. Therefore I sent the email to ask you how to group the module. Later I found, it is under >> Edit >> Group.
Thanks
Lin

Coilcraft's shipping is $6, with Ground, about two days.
I just ordered some baluns from coilCraft for the expended log detector.

7770. SMA connector problem

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-03 23:59:04 UTC
From: Sam
Topic: 7770 Message: 7770

I had a problem with an SMA connector that I thought I'd mention in case someone else runs across it. My TG gets to the outside world through a panel-mount female-female connector. A cable attaches to the inside, coming from the TG amp. While I was messing with the TG amp, the TG output came and went. Sometimes it was strong; sometimes is was very weak at low frequency and modest at high frequency.

It turned out that when I screwed the inside cable to the panel connector a good connection was made until I made it very tight (hand-tight; I wasn't over-tightening). At a certain tightness, the cable center pin apparently was suddenly not making contact with its mate in the female-female connector, or maybe the problem was internal to that connector. All the parts I could see looked fine. I still can't imagine how this was happening, but I replaced the connector and all is fine.

The connector was one of the inexpensive Chinese types.

Sam W.

7771. Cal Source

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-04 14:37:38 UTC
From: Sam
Topic: 7771 Message: 7771

The "1MHz Cal Source" provides an output whose precise level can be determined with an ordinary voltmeter. It was originally intended to operate at 1 MHz (from an an-board oscillator or external source). But, due to the zero-response interfering with low level signals at 1 MHz, it is actually better to use 2 MHz. The circuit divides the input frequency in half to get a 50% duty cycle, so getting 2 MHz output actually requires a 4 MHz oscillator or input. I'm going to rename this board the "xMHz Cal Source". It should be precise with 1-5 MHz output, though it will be functional far beyond that. Just remember to use an oscillator at twice the frequency of the desired output.

You can use this directly as the signal source for path calibration, adding attenuation as necessary. Unfortunately, this won't work for phase calibration since you can't synchronize the cal source with the MSA phase. (You can use the TG to feed the cal source, but its frequency will get divided by two.)

If you have an external signal source, you can use this to calibrate its output level at 2 MHz. Just measure the cal source on a very coarsely calibrated MSA and then measure the signal source and adjust its output until it equals that of the cal source. The true output of the signal source then equals the true output of the cal source (determined by the voltmeter measurement--forget what the MSA is displaying.) Then use the signal source for mag calibration. Not phase calibration, unless you can phase lock the signal source to the TG.

Or, you can use the cal source to calibrate the output level of the TG, and use that for both mag and phase calibration. In this case, you will have to attenuate the cal source output to get it down to the TG level, or amplify the TG to get it up to the cal source level (about 0 dBm).

You can also do the comparison of signal levels with a scope or power meter instead of using the MSA.

Hi I am using the Proxxon KS-230 bench saw . This sells for around 100$ US. I am using a Saw blade, with the following markings 58x 0.5 x10 Z=80 Max 8000 per minute Mat HL. After cutting two sets of boards the blade is still very sharp. Mind your fingers! Proxxon do a range of blades for different work.

The unit is very small and packs away nicely. Ideal for all those model engineering and Ham radio jobs.

No I have no connection with Proxxon just a satisfied customer!

7774. Frequency Multiplier

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-05 02:48:18 UTC
From: william
Topic: 1100 Message: 7774

Hi All,
Since the latest group buy of board contained a PWB for the SRD Multiplier, I decided to update the page:

http://scottyspectrumanalyzer.com/srd/srd.html

There are a few more things I want to do with it. The schematic and layout need updating to conform to SLIM requirements. But, for now, I thought the descriptions needed clarification.
You will notice that I stated on that page that replacing the MSA's PLO 2 with a multiplier is not justified unless PLO 1 is modified to decrease its phase noise. There have been a couple of builders who have expressed interest in using a YIG synthesizer for PLO 1. This is where the multiplier would be highly beneficial for PLO 2.
As was stated, the multiplier is experimental. It really is a lot of fun to dicker with (full of voodoo, too).
Scotty

7775. Amplifilter

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-05 17:17:33 UTC
From: Sam
Topic: 7775 Message: 7775

I decided to move the amplifilter to the top of the list, and built it with four crystals having a total frequency spread of 66 Hz and not particularly good Rm values. I did not include any of the trimmer caps and did no tuning whatsoever. The results are shown here:

<http://groups.yahoo.com/group/spectrumanalyzer/photos/album/271352628/pic/639082963/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc>

The graphs are uncalibrated, so everything shows 11.7 dBm below actual value. The filter has BW=700 Hz and insertion loss of 4 dB. Ultimate attenuation is beyond 100 dB. It has no ripple whatsoever, and the peak is just slightly asymmetric. Some tuning could reduce the bandwidth and the op amp gain could be adjusted to eliminate the loss, but this is quite nice the way it is.

The schematic shows 1 nF series capacitors on the crystals but those should be 10 nF, which I used--these are the capacitors you would tinker with to adjust crystal frequencies. Before adding the crystals, I jumpered across the crystal pads (from the input of each pair to its output) and checked the response with just the impedance matching components and the op amp, which peaked a little below 10.7 MHz, so I need to adjust the impedance matching--I'll just lower the inductor value. The impedance matching components actually do very little impedance matching; they are there mainly as lowpass filters.

Note also that I used no fencing whatsoever, and the crystal leads are exposed a bit on the bottom of the board, to make it easier to remove the crystals to experiment. Yet there is no apparent blowby problem.

I changed the impedance matching inductors without much effect. Changed the 10 nF cap on the lowest frequency crystal to 1 nF and now have a very symmettric response.

Sam,

The trimmer cap values that you show in the amplifilter schematic, are they
the "target" value or are they the max value of the cap?
Obviously, in the first case the max value will have to be somewhat larger.

From: Sam
Topic: 7775 Message: 7778

Jim,
They are target values. However, I left them out completely.

I have now made just a few adjustments to the original and have achieved a 525 Hz bandwidth with a very nice profile. See:

<http://groups.yahoo.com/group/spectrumanalyzer/photos/album/271352628/pic/2136370248/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc>

I did end up "trimming" the 330 pF caps by putting 100 pF on top of them. This reduced the coupling and improved the peak shape. This may be unnecessary for those using the crystals from Scotty and Jerry. Because of the reduced coupling, the loss increased so I increased the op amp gain.

The response is absolutely free of filter spurs (only my tiny MSA 10.7 MHz spur) from 1 to 100 MHz, except I got a small glitch at 75 MHz that is due to leakage between the two pairs of filter cans and goes away if I hold a piece of metal to the ground plane between the pairs. (I still don't have the cans firmly against the ground plane.) Even without fencing, that was the only visible leakage glitch and everything is clean down to at least -105 dBc.

This thing performed very well out of the box, and these minor tweaks made it as close to perfect as I could want. I actually got the bandwidth down to 400 Hz by reducing the coupling a little more, but that introduced a 1.3 dB ripple near one 3 dB point. Not a big deal, but I decided 525 Hz was narrow enough for me and I went for the cleaner shape.

Sam, It looks like the OPA695 works at 5 VDC instead of 8. Or do you think
is better to push it to 8? I can't find the 842.

From: Sam
Topic: 7775 Message: 7781

Interesting. I just finished sending an email to Scotty on a related topic. The OPA695 is a fabulous op amp, but I don't think it has enough voltage swing for this purpose, when operated at 5V. When the MSA has max input, the op amp has to be able to handle whatever voltage swing is created at the filters. I use the Expanded Log Amp, which uses less IF2 amplification, so this is less of an issue.

One limitation of op amps with large signals is that if you want a 50-ohm output, you have to insert a 49.9 ohm series resistor, and let the op amp swing twice the voltage of the load. That's the downside of the miracle of op amps having near-zero output impedance. So you sometimes run into voltage swing problems where you wouldn't expect it.

Worst case would be that the very narrow filter max out at a lower MSA input level than other filters. Maybe -5 dBm instead of 7 dBm. That's probably not a huge deal. The amplifilter allows an 8v LDO regulator, or a 78L05 or 78L06. I'm actually using +5V with an OPA356 (semi-rail-to-rail). Using +8V would expand the range, but the OPA356 can't take that voltage. So the schematic shows an OPA842. But that op amp is not rail-to-rail, so it may have no better range at +8v than the OPA356 does at +5v. And then there are slew rate limitations....

A couple of years ago, you could search data sheets for the right op amp and then go to Digi-Key or Mouser to buy it. Now, the range of available op amps is far more limited.

At the moment, I think the best options are the OPA356 at +5V or the OPA695 at +8V. When the OPA842 is available again, that is also a good choice at +8v. I'm using the OPA356 because it is cheaper, though I would say there is hardly an RF application imaginable where the OPA695 is not the op amp of choice.

Sam W.

The datasheet "absolute maximum rating" for the OPA695 is +/- 6.5 Volts.

Topic: 7775 Message: 7783

Yes, the OPA695 can do fine with a wide range of supply voltages. The question is whether its output has enough range with a 5v supply. The output can swing within 1.4v of the rails, which eliminates the top and bottom 1.4v, leaving 2.2v of voltage swing. If you have a series 50 ohm resistor leading to a 50 ohm load, that gives 1.1 Vp-p of swing at the load. That's about 5 dBm. That is plenty with the Expanded Log Detector using 28 dB of IF2 fixed gain, but maybe not when using the standard 40 dB IF2 amp.

It would be a simple matter to use a 6v supply rather than 5v, by just using a 78L06. That entire extra volt becomes available as output swing (half of it at the load). The PCB also allows for an LDO regulator that would provide 8v. Or, you could just accept that the top end of the MSA input would be lower with this filter (not that normal levels would suddenly cause harm; the response would just flatten). The MSA responds to signals above -5 dBm, but in SA mode they are highly distorted so their loss in this filter path might not be a big deal.

If the OPA695 is what you have, I suggest giving it a try. You can always change the supply regulator later if necessary. You will certainly get good performance over most of the signal range; it's just a question of where it tops out.

From: Sam
Topic: 7775 Message: 7784

The amplifilter provides a potential method to lower the noise floor, viewed from the MSA input. If you increase the amplification by 10 dB, you get a stronger signal without much more noise, due to the filtering by the pair of crystals that follows the amp. The op amp output will be inherently limited and will not damage the crystal pair that follow it. Rather the response for high end signals will simply flatten out. You could probably lower the noise floor by 8-10 dB by this method, using the current board. If the board were revised to include two op amps, you could achieve 30 dB. Of course, everything you gain at the low end you lose at the top end. But it might be handy to have one path that can detect extremely low level signals.

This idea is not unique to the amplifilter. You could add an amplifier to any of the four paths to shift its dynamic range to a lower low end and a lower high end.

P.S., Based on a conversation with Scotty, the OPA695 should come within a few dB of the ideal max output with a 6v supply. 8v would give it everything it needs. But if you want to go for max gain, I would use the OPA847 with 8v.

Thanks for the info Clive.

Anyone know of a US source for this saw? An internet search turned up numerous European dealers as well as some hits in Australia and New Zealand. But no US source.

Help.

I couldn't find that model but here is something like it. Maybe Clive
can let us know if this looks familiar, could be just a model number change.

http://www.amazon.com/Proxxon-37006-115-Bench-Circular/dp/B0017TO806/ref=sr_1_1?ie=UTF8&s=hi&qid=1299435099&sr=8-1

Steve-

Harbor Freight sells a small 4" table saw the may work well for this purpose.

I have used the Harbor Freight (aka cheap Chinese junk)4 inch Mighty-Mite saw with a diamond blade.

http://www.harborfreight.com/catalogsearch/result?category=&q=mighty+saw

http://www.harborfreight.com/4-inch-diamond-blade-95315.html

It works but one had better expect the thing to slow down due to an under powered motor.

The saw was around $35 and the diamond blade $5.00

If you don't mind working slow, this will do the job for you.

7789. Amplifilter schematics,

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-06 20:38:51 UTC
From: davidhooau
Topic: 7789 Message: 7789

Folks,

Could someone please point me in the direction of the amplifilter schematics?

Also, on Jim's filter panel (thanks Jim!!) are a pair of ceramic RBW filters which appear orphaned from the parent documentation.

Thanks,

davidh

Hi Scotty,

Many thanks for this. You were correct regarding the +11dBm data point; I had failed to remove that entry from an earlier test.

My LD is well saturated by about +12dBm at J1, which is consistent with figures 8 and 11 in the data-sheet. I'd appreciate feedback from other builders regarding this.

Cheerio,

davidh

> ADC = 65534, dbm = 137.81, Phase = 0
> delete any other sets of values
> 4. Click Cleanup, then click Save File
> Â (Of course, the -104 and 137 dB points are not obtainable, but the values establish data points for the software to calculate "real" power inputs.)
> 5. From this point on, you can command the MSA to use Path 2 and the Magnitude will indicate the exact power on the input to the Log Detector, NOT the power input to the MSA. It should be fairly accurate (+/- .5dB) from +15 dB down to -80 dBm. Below -80, the Log Detector is operating in its non-linear area, but it will certainly indicate data. Due to some error from MSA to MSA ,your mileage may vary!

I would also like the same type of data for a completed MSA (front end input vs Magnitude bit count). We "sorta" have the latter in the Path 1 pre-loaded table. But it is too coarse. I will perform a calibration of the Log Detector and create a table and use it for a pre-load for Path 2. This will help builders who are testing as they build.

>
> > Ã☐ If you (or anyone) would like to, perform a Mag Cal on your Log Detector and send me the results to compare to what I get. Use 10.7 MHz +/- 1 MHz. Go from +15 dBm (or as high as you can) to -110 dBm in 5 dB or 10 dB steps (or finer steps if convenient to you). Your table will be LD input power (in dBm) vs. Magnitude bit count. Of course, the Magdata is available in the Variables Window.

7792. Re: Amplifilter schematics,

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-06 21:55:13 UTC
From: Sam
Topic: 7789 Message: 7792

I think Jim distributed it to those who bought the board, but it appears on Sheet 2 of the 4-crystal filter file. I just tweaked it a bit and added some build notes, and posted it in the Files section under Amplifilter.

I think Jim's board contained a dual ceramic filter and also several single ceramic filters. The dual filter is just two cascaded filters, no coupling capacitor and LC impedance matching on each side to whatever the manufacture specifies as the filter impedance. The single filter is the same concept; I don't know if there are actual schematics. Each can use the old leaded style filters or the newer SMT types.

The single ceramic board can also likely be used with the MiniCircuits LFCN lowpass filters that I mentioned in a recent posting, or with the similar HFCN highpass filters.

Sorry your having problems locating the Proxxon KS230. Try the link below for suggested outlets in the USA

http://proxxonusa.com/

and click on customer services.

I have emailed them as well asking for suggestions.

Stick with it I can assure you that the product is worth it.

Good Luck and 73 Clive GW0PPO

7797. RBW Filters

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-08 13:29:16 UTC
From: Sam
Topic: 2188 Message: 7797

A while ago someone posted a photo of an RBW filter made with 2 or 3 ECS-10.7-7.5 cans. Does anyone know where that photo is?

I have put together a layout of a board that combines the RBW filter switch and four filters. Two are dual ceramic filters, probably 300 kHz and 61 kHz. One is a 3-can MCF filter, probably 7.5 kHz. The fourth is the amplifilter, which in my case came out to 525 Hz. Half of the switch-to-filter connections are made with traces. The remaining four would be made by direct-soldering 0.086" coax. This eliminates sixteen SMA connectors (8 on the switch, 2 on each filter), not to mention the mating connectors on the cables. It is still possible to add SMA connectors in case you want to make a substitution for one of the filters.

I have the board pretty much finalized, though I would like to hear from anybody who used the ECS filters to be sure I get the circuit right. The board is 3.6" x 2.4", which means it fills an ExpressPCB Miniboard. Three could be ordered at a cost of $20 per board. If there are interested builders, I can supply the layout, though I don't plan to replace my existing filters with this board and I don't want to be in charge of a group buy.

The RBW filters have always been every-man-for-himself, with people using whatever they can find or build. At this point, it seems to me that the ceramic filters are so simple that it is hard not to use them for the two widest filters, and the amplifilter is so simple and narrow that it is hard not to use that for the narrowest filter. The second most narrow filter is less well defined, and I can see some wanting to build it with the 5-crystal board, some with MCF, and some using canned filters. The reason I went for the MCF filter for this board is that it is the most compact and fits the available space. I will try a layout using the 5-crystal board in place of the ECS.

From: Sam
Topic: 2188 Message: 7799

Things are looking better. I modified the layout to hold a 5-crystal filter, similar to Scotty's but I had a bit more room so I could add some trimmers and use a layout that will require a little less internal shielding. This replaces the layout for ECS cans, but if desired those could be used on the crystal layout. So the current board, which still fits the MiniBoard size, contains the RBW switch and four filters--two ceramic, the 5-crystal layout and the amplifilter. Note also that my 5-crystal layout is slightly larger than single-SLIM size, so if a different layout is desired for that filter, a regular SLIM module could be mounted right on this board, on top of the 5-crystal layout.

From: Sam
Topic: 7800 Message: 7800

If anyone has a spare set of the 10.11 MHz crystals they could send me, I would appreciate it. I'll test them in the amplifilter. I can send them back to you. Or build the amplifilter and send it to me and I'll fine tune and return it (but send the crystals separately unless you have marked the frequency deviations of each). Or fine tune it yourself and let me know what component values you used.

Sam W.

7801. MSA collection PWB from last year

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-08 22:42:13 UTC
From: Steve
Topic: 7801 Message: 7801

I have the MSA collection PWB from a group buy in July, 2010. [Yeah, I'm a little slow getting around to things :-)]

There are three small PWB's each labeled F1 along the top and LFCN/HFCN along the bottom. What are those PWB's to be used for?

There are two small PWB's which look somewhat similar. One is labeled SER, the other is labeled SHNT. What are those PWB's to be used for?

With respect to the PWB labelled "Dual Ceramic Filter," is there a schematic somewhere for that board? Any documents regarding how to use it?

Thanks.

Steve K8JQ

The LFCN boards are for low or high pass filters using the MiniCircuits LFCN or HFCN devices. You just solder them on the board with connectors, and maybe capacitors.

SER and SHNT are for series and shunt fixtures, which are just attenuators on each end with a connection for the DUT in the middle. On SER, the DUT goes in series between the attenuators; on SHNT it goes shunt to ground. These can be used in place of bridges in Reflection mode, with or without OSL calibration. The shunt fixture is best for low impedances; series is best for high impedances.

I don't know if there is a schematic for the dual ceramic filter, but it is pretty self-explanatory. Two ceramics are cascaded directly with no coupling component, and LC impedance matching is stuck on each side. You design the match with RFSim99 based on the impedance of your filter, usually 330 or 470 ohms.

That's the one. Thanks. Its a File rather than a Photo, which is why I didn't find it. I didn't realize that for the third MCF can you used 15 kHz rather than 7.5 kHz, which I imagine you did because its spurious response wouldn't line up with that of the other two cans. Good idea.

Sam,

Thanks for the info!

> SER and SHNT are for series and shunt fixtures, which are just attenuators on each end with a connection for the DUT in the middle. On SER, the DUT goes in series between the attenuators; on SHNT it goes shunt to ground. These can be used in place of bridges in Reflection mode, with or without OSL calibration. The shunt fixture is best for low impedances; series is best for high impedances.
>
> I don't know if there is a schematic for the dual ceramic filter, but it is pretty self-explanatory. Two ceramics are cascaded directly with no coupling component, and LC impedance matching is stuck on each side. You design the match with RFSim99 based on the impedance of your filter, usually 330 or 470 ohms.

7811. VGA VMAG reference

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-10 18:49:55 UTC
From: davidhooau
Topic: 7811 Message: 7811

Hi folks,

The schematics for Sam's VGA (9/25/10) show a 2.5V shunt reference and a resistive divider to set the VMAG level for the AD8330, which makes sense to me.

The PCB (9/23/10) has the ref diode in series between R5 and R4, which will set VMAG to 833mV instead of the desired 1.2V (approx).

Can Sam please confirm that the schematics are indeed correct?

An easy fix would be to short pins 2 and 3 of the SOT-23 and then solder the diode (rotated by 180deg) between the input trace from R5 and ground.

Cheers,

davidh

You are right; the PCB has an error. This was pointed out before, and I'm sure I corrected the PCB, but I now can't find the fixed version. So I did a new fixed version and put it on my website in place of the old one. The schematic is correct.

As far as using the existing board, be sure pin 2 gets grounded, pin 3 gets connected to a line connecting R4 and R5, and pin 1 is floating or grounded, all as shown on the schematic. Pin 1 is the pin all by itself on one side; then you number 2 and 3 clockwise. All this can be done by rotating the diode and making sure the trace leaving R4 makes it all the way to R5.

Sam W.

Sam
The third 15kHz MCF is just used to suppress the spurs. It works very well.

> > >
> > > I have put together a layout of a board that combines the RBW filter switch and four filters. Two are dual ceramic filters, probably 300 kHz and 61 kHz. One is a 3-can MCF filter, probably 7.5 kHz. The fourth is the amplifilter, which in my case came out to 525 Hz. Half of the switch-to-filter connections are made with traces. The remaining four would be made by direct-soldering 0.086" coax. This eliminates sixteen SMA connectors (8 on the switch, 2 on each filter), not to mention the mating connectors on the cables. It is still possible to add SMA connectors in case you want to make a substitution for one of the filters.
> > >
> > > I have the board pretty much finalized, though I would like to hear from anybody who used the ECS filters to be sure I get the circuit right. The board is 3.6" x 2.4", which means it fills an ExpressPCB Miniboard. Three could be ordered at a cost of $20 per board. If there are interested builders, I can supply the layout, though I don't plan to replace my existing filters with this board and I don't want to be in charge of a group buy.
> > >
> > > The RBW filters have always been every-man-for-himself, with people using whatever they can find or build. At this point, it seems to me that the ceramic filters are so simple that it is hard not to use them for the two widest filters, and the amplifilter is so simple and narrow that it is hard not to use that for the narrowest filter. The second

most narrow filter is less well defined, and I can see some wanting to build it with the 5-crystal board, some with MCF, and some using canned filters. The reason I went for the MCF filter for this board is that it is the most compact and fits the available space. I will try a layout using the 5-crystal board in place of the ECS.

From: davidhooau
Topic: 7814 Message: 7814

Folks,

I've built an amplifilter using 4 crystals matched within 20Hz. You'll find some happy snaps in the davidh photo folder, and I'd like some advice on tuning it please. The images were taken using DDS1 as a signal source, as I don't yet have a good RBW filter to use the SSA as a VNA. The filter has no shielding or fences yet.

> There's an obvious asymmetry, which I suspect is due to the input and output matching networks being incorrect. Prior to the crystals being installed, I jumpered across the 2 crystal pairs and found the overall LPF response a little on the low side (maybe 1dB down at 10.7MHz). Would this explain the asymmetry?

> There are some little peaks visible in the 300kHz and 3MHz wide traces, always at the same locations. How might I approach fixing these up?

Many thanks,

davidh

Hi David,
 You have a good looking 600 Hz filter. The asymmetry is as expected. The upper skirt will have a steeper response than the lower skirt, due to each crystal's parallel resonance. This occurs about 20 to 30 Khz above center frequency. There is nothing you can do about that, and there is no need to have a perfect symmetric response, anyway.
  There looks to be a very minor skirt perturbation at -90 dBm. I'm inclined to believe that your magnitude calibration between -80 and -100 dBm is not exact, and that would explain it.
  The "little peaks" are DDS spurs. They don't need "fixing" because they will not be there when you place this filter in one of your Resolution Paths.
 The DDS does make a fantastic, low noise signal source. But its downside is lotsa spurs. This is why the DDS module contains a crystal filter, to reduce those spurs before reaching the PLO module.
 Bottom line, do nothing other than add your shielding and take data again. I'm thinking you may see no difference at all. This is a good looking response, as is.
Scotty

Yes, this is excellent, exactly the way it should be. In actual use in the MSA, I don't believe you will ever see the profile of the narrow filter response below about -65 dBc (due to phase noise effects), so the minor asymmetry at low levels will become invisible. The important factor is that the top is very symmetric and has no ripple.

I'm curious as to your component values. Did you change any of the schematic components? Did you include the trimmers? (either as trimmers or as fixed caps?) My LPF also peaked a little lower than the design value. I decreased the inductors to 560 nH which moved the peak upward, but had minimal effect on overall filter performance.

I can't tell the insertion loss from the SA scan, but if it is too high or low (-2 dB is a good target) you can adjust the op amp gain.

If you prefer a flatter top, you can increase the coupling by reducing the 330 pF caps. That will also reduce the insertion loss and affect the ideal op amp setting. I like a somewhat flattened top, but not if it causes asymmetry or ripple--sometimes flat tops get tilted. Currently, mine looks just like yours.

My goal was to design a narrow filter that would work well "out of the box" without a lot of sensitive adjustments. So far so good.

One other thing you might test is whether you can get the output up to 10 dBm. With a +5V supply and the OPA356, mine maxes out at 9 dBm, which is fine. For anyone using the Expanded Log Detector, the max output is not be an issue at all.

Sam W.

From: davidhooau
Topic: 7814 Message: 7817

Hi Sam and Scotty,

So much to learn (but it's so much fun)!

I can get +12dBm from it, which is where my LD saturates, using an OPA842 and an 8V rail; this is using an external sig gen at the centre of the filter. When I get a good second RWB filter working, I'll test again in VNA mode.

Using schematic specified components around the amplifier, insertion gain is +1.8dB.

I have a very limited stock of Ls and Cs (I'll end up spending a few hundred on the SSA and lots more on a decent parts bin), so most of the capacitor values are way off. No trimming performed at all yet.

L1, L2: 680u nom, R: 2.4 Qmin: 22@30MHz
C1, C8: 490pF
C2, C7: 440pF
C4, C5: 320pF
C3, C9, C13, C6: 10nF

Are all of the shields required, or should I hold off until further experiments are performed?

Cheers, and thanks!

davidh

7818. Q of notch filter

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-11 21:23:21 UTC
From: Sam
Topic: 7818 Message: 7818

Here is a very basic electronics question. The Q of a filter equals center frequency over bandwidth. The bandwidth is determined as the frequency difference between the 3 dB points.

The question is, for a notch filter are the "3 dB points" 3 dB down from the top or up from the bottom of the notch.

Several sources indicate that you go 3 dB down from the top whether you have a band pass or band stop filter. For example,

<http://www-k.ext.ti.com/SRVS/Data/ti/KnowledgeBases/analog/document/faq\
s/q.htm>

makes this statement:

"Q is defined as the Quality Factor of a bandpass or notch filter. It is defined as the center frequency of a filter divided by the bandwidth. The bandwidth is the frequency of the upper 3 dB roll-off point minus the frequency of the lower 3 dB roll-off point."

Now, the definition of Q using 3 dB points has to jibe with the definition for LC filters, using reactance and resistance. For a series LC filter, the unloaded Q is the reactance of L at resonance, divided by the series resistance.

Here is some data from RFSim99: Place a series LC circuit shunt to ground between a 1 kohm source and load (so it is nearly unloaded). Make C=1 nF and L=1 uH with a series R of 1 ohm. It resonates at 5.04 MHz. The reactance of L at resonance is 31.7 ohms. Therefore Q by the reactance/resistance method is 31.7/1=31.7.

The 3 dB bandwidth is 0.157 MHz if you use points 3 dB above the bottom of the notch. It is 80.9 MHz if you use points 3 dB from the top (i.e. absolute -3 dB level). Dividing center frequency by bandwidth gives you Q=32.1 for the from-the-bottom points and Q=0.062 using the from-the-top points.

Obviously, you need to measure the 3 dB points relative to the bottom of the notch if you want to get the same Q value using freq/BW as you do with reactance/resistance, right?

Ah, but here is the catch. I stated above that I used 1 kohm source and load so the LC would be nearly unloaded, but if you view those 1 k resistances as becoming part of the series LC circuit, higher resistance actually creates more dissipation and reduces the Q. In fact, the Q=0.062 value calculated above using absolute -3 dB points is almost exactly L reactance (31.7) divided by series resistance (in this case

considered to be 1 + 1k||1k = 501 ohms).

If you view the notch starting with a low source and load resistance and then increase those resistances, the width of the notch at the top becomes wider and wider, reflecting the lower Q that results when you include the source and load (in parallel) as part of the series resistance of the series LC circuit. The bottom of the notch, however, initially narrows somewhat as the source and load increase, but once they get much bigger than the 1 ohm series resistance there is not much change. Large source and load make the top wider and small ones make the bottom wider.

My conclusion is that you could define Q using either the top or bottom pair of 3 dB points, and that definition will be consistent with the reactance/resistance definition, provided that you properly calculate the resistance. If you use the top 3 dB points, the effective series resistance of the LC circuit is the sum of the 1 ohm explicit series resistance plus the parallel combo of the source and load (meaning large source/load values reduce Q). If you use the bottom 3 dB points to define Q by the bandwidth method, you need to treat the source and load as being a "parallel load" on the circuit (meaning large source/load values increase Q); I can understand that parallel treatment qualitatively but I'm not sure of the mathematics--how do you combine the effects of the 1 ohm series resistance and the 500 ohm parallel resistance (500 being 1k||1k).

It does appear that the formal definition of Q for a notch filter uses the top 3 dB points. That's what Transmission mode RLC analysis currently uses. It has the drawback that the 3 dB points are typically very far apart--you get Q values like the 0.062 value above. If those points are used, you are much better off using a very low impedance fixture, which will give a narrower notch.

A corollary of all this is that if the parallel combo of the source and load resistances is at least 10 times the internal series resistance of the LC circuit (here, 1 ohm), then Q determined with the upper 3 dB points will be the loaded Q (QL) of the circuit, and Q determined with the bottom 3 dB points will be very close to the unloaded Q of the circuit.

I'm still trying to decide how all this affects the optimum way to perform RLC analysis.

Sam W.

If you get 12 dBm, you're in good shape.

I hope your "680u" inductor is really "680n".

A lot of shielding is provided for, because I didn't know how much would be needed. The shields don't have to connect to the lid to be effective at this frequency, so they are not hard to add. It may be that no internal shielding is needed; however, I would at least add enough that area from the board input through the input of the second crystal is isolated from the rest of the circuit. I wouldn't add them until you're not likely to have to change any components, because they may get in the way.

I like a somewhat flattened top, but not if it causes asymmetry or ripple--sometimes flat tops get tilted. Currently, mine looks just like yours.

7820. VGA noise filter

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-12 03:59:21 UTC
From: davidhooau
Topic: 7820 Message: 7820

Folks,

Does anyone has access to the data-sheet of the sfecv10m7cq that's been specified for the VGA noise filter?

I've posted the response of the sample I built in the photo section, but without the data, am in no position to make a about its acceptability.

Thanks,

davidh

David

Try this link, Not sure it is what you want but was the only thing that came up for a search on that part number.

http://datasheetz.com/data/Filters/Ceramic/490-1231-6-datasheetz.html

Oh Wise Ones,

I've posted a happy snap of my SSA's first "real" scan: "ssa_100M_first_image" in the davidh photo folder. I'd really appreciate comments on how it looks.

> MXR1 has 2.5dB attenuator built into input.

> Cavity filter needs work! 6.5dB insertion loss, 2.6MHz BW.

> 40dB IF amplifier

> Sam's wonderful amplifilter

> System calibrated (roughly) and levels shown at LD input. Overall levels are about 3dB more than I expected which I'll work on tomorrow..

> LO2 isolation amplifier in situ.

> TG buffer in situ.

> Fences in place, but no lids on any of the modules yet.

I'd like to understand the signals at markers 1 and 2, and confirmation that the LO1 and LO2 phase noise isn't excessive.

Many thanks.

davidh

Attachments: 1 described; binary payloads are missing from this source WARC

Look at the digikey # 490-1231-1-nd. This part works fine, I use it.
They have a datasheet on their site. See the attached.
The complete part number is SFECV10M7CQ0C01-R0.
10.7MHz 500kHz bandwidth.

Hi David,
 Good going. Phase noise at the bottom of the skirt looks like -90.8 dBc/1Hz. Right on target for -91. If your spurs at the markers are consistent, then go into the Sweep parameters window and select the spur test. If they go away or change position, do not worry about them.

David,
In the SamW--RBWFilters photo album are photos of various dual ceramic filters, one of which is the one you mention. That shows the response I got. In the Files section, in RBW Filters folder, I just posted specs for Murata Cerafil ceramics. It doesn't have our exact part number, but SFECF10M7CQ00-R0 seems to be similar.

From: Sam
Topic: 7820 Message: 7826

David,
I should also point out that for the noise filter the shape of the top is not critical, as long as it is not so ugly as to impose ripple on the narrower RBW filters that fit within its bandwidth. Your noise filter has a reasonably curved peak response. For example, if you use a 7 kHz RBW filter, There will be no signals very far outside the 7 kHz bandwidth, so the response of the noise filter at, say, +/-30 kHz from center is irrelevant as far as shaping the signal image. Within the range that a 7 kHz RBW filter cares about, your noise filter is essentially flat. For a wide RBW filter, like 300 kHz, the curvature of the noise filter peak will slightly round the effective shape of the RBW filter and slightly steepen its skirts.

The spurs don't matter because the total noise within them will be small, as long as your impedance matching is the normal LC low pass topology, causing the attenuation to gradually increase beyond maybe 15 MHz. That means the vast bulk of noise power is between the -3 dB points. These spurs never show up on screen, because no signals at those frequencies reach the noise filter.

If you wanted to play with the shape, you could add or remove a bit of capacitance from the impedance matching and see what happens. I don't think the ceramics are very sensitive to such capacitance changes, so you might have to make large changes to have an effect. (e.g. change by 20 pF rather than 2 pF). The optimum setting might involve an increase on one side and a decrease on the other.

Hi Scotty,

Thanks for your encouraging words.

The spurs were indeed from the DDS. Soon I'll put covers on all of the slims and search for some real spurs in earnest.

That looks good and should work fine. There is probably no need for further adjustment, but another way to adjust the ceramic filters is simply to replace one or both ceramics. They are cheap, and the tolerance for their center frequencies is quite large, so you might be able to move the center frequency upwards with a different filter.

I was forgetting that the noise filter is a single filter, which would make substitution even simpler.

7831. Amplifilter at 10.111 MHz

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-13 17:19:27 UTC
From: Sam
Topic: 7831 Message: 7831

I swapped out the crystals in my amplifilter to use a set that Jerry matched. I restored the components to match the schematic without trimmers, with the op amp gain increased a bit. I left the 10.7 MHz impedance matching in place, with the original 680 nH inductor.

This particular set is almost perfectly matched, with a spread of 3 Hz. The results are outstanding and are shown here:

<http://groups.yahoo.com/group/spectrumanalyzer/photos/album/271352628/pic/332694597/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc>

The bandwidth is 244 Hz! The peak is rounded, ripple-free and just slightly asymmetric, with insertion loss near zero. The passband is only 7 kHz wide at -100 dBc.

This beats the 525 Hz bandwidth with my 10.7 MHz crystals. I don't know if the difference is the smaller spread in these (mine had a 66 Hz spread), or the characteristics of the crystals (mine and Jerry's are a factor of two different in Lm). But the main point is that it appears you can get very good results with the standard schematic with very different sets of crystals.

I'm going to change a crystal or two to increase the spread and see what happens.

Sam W.

Well, this was easier than I expected. I was anticipating doing a lot of experimenting to see how well I could correct problems arising from having a crystal that was not well matched to others in the set. So I replaced one of the crystals in the well-matched set with one that is lower in frequency by 90-125 Hz. I don't know what the spreads were in all of Jerry's and Scotty's sets, but from the ones I know of I would guess that all have spreads less than 50 Hz. So I figured having a crystal off by >90Hz would be an extreme test, and with a 244 Hz bandwidth would cause big problems that would require correction.

However, when I substituted the low-frequency crystal, the bandwidth hardly changed, and all that happened is the peak got skewed a bit to the left side and the insertion loss increased by 1.5 dB. There is still no ripple. Photos are in the same album as the photo of the original, so you can look and compare.

My conclusion is that anyone who got a set of the 10.111 MHz crystals could build an amplifilter that would provide very narrow bandwidth with no or very little tinkering. At this bandwidth, phase drift is likely high, but this bandwidth is most useful for high resolution in the SA (though phase noise will limit the dynamic range in which the narrowness provides a benefit), or for VNA scanning of the skirts of steep filters, where phase is not relevant (or at least precise phase is not).

I would guess that with a bandwidth more like my 525 Hz, you might get by with crystal spreads of 100 Hz with no need to tinker. That makes frequency matching a lot easier.

Anyone using the Expanded Log Detector likely can't use the 10.111 MHz filters, because all RBW filters have to fit within the bandwidth of the noise filter. But you can still get narrow bandwidth with 10.7 MHz crystals. Mine was 525 Hz--maybe crystals with Lm more like Jerry's would be narrower but I'm very happy with what I'm getting.

I was not aware that the 10.111 MHz crystals are SMT, but it was no big deal to bend the leads into the normal configuration (and remove the insulating pad), though they are flat rather than round and just barely fit through the holes in the PCB.

I added a 330 pF series cap to the low-frequency crystal, and pretty much corrected the response. No image though.

One final test, shown in the photo album. I did a scan with 3 well matched crystals and one that was 275 Hz low, which is a huge deviation for a filter with bandwidth near 250 Hz. The shape became distorted, though not horrible, and the insertion loss increased by 5 dB. All crystals had 10 nF series caps, which are essentially invisible. I reduced the series cap on the low crystal to 200 pF and largely solved the problem, though about 0.3 dB of ripple remained.

So significant frequency deviations are correctable, though not perfectly so.

Topic: 7831 Message: 7834

The photo album SamW--RBW Filters now contains the results of my final tweaks of the amplifilter using 10.111 MHz crystals. I went back to the well-matched crystals, since all the sets that were sent out are quite well matched. (In fact, you only need 4 of the 5 crystals, so you can measure them and toss the outlier if you want to improve the match, though probably not necessary.)

I basically reduced the coupling by increasing the two coupling capacitors, and reduced the value of R1 to 33 ohms. The bandwidth is now 220 Hz and the shape of the peak is very nice. I am confident that most people will get similar results with these component values without additional tweaking, or at most having to adjust the op amp gain. Be sure you use good inductors, with Q>20 at 10 MHz. There are some available in 0805 size.

I think the key to the narrow bandwidth is that these crystals have Lm near 20 mH, compared to the 10 mH of my 10.7 MHz crystals. The op amp does not directly contribute to low bandwidth; it just makes it easier to maintain a good shape without needing fine tuning to deal with all the interactions among the crystals.

It occurred to me that the shape of the bottom half of the skirts is probably even narrower than shown in the scans, because I used a 2 kHz RBW filter, which used to seem narrow but is almost 10 times the bandwidth of the amplifilter. But that shouldn't affect the accuracy of the measurement of the amplifilter bandwidth.

I will soon post a new schematic with the final values. I am now going to return to the 10.7 MHz crystals and see what I can do.

7835. Amplifilter at 10.7 MHz

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-14 19:18:01 UTC
From: Sam
Topic: 7835 Message: 7835

After I put in the missing impedance match component, my bandwidth with the 10.7 MHz filter became 590 Hz, which is a bit of an increase. The impedance match is almost meaningless, as it matches 50->65 ohms and is mainly intended as a low pass filter, so I could tinker with it, but I'm going to stick with 590 Hz. Which is also nearly what David got with 10.7 MHz crystals from an entirely different source, so I'm pleased with the consistency.

Anyone who wants a narrower bandwidth near 10.7 MHz might have to find crystals with Lm much higher than 10 mH. I tested a 10.73 MHz crystal and got 10 mH. I tested a 10.368 MHz crystal and got 22 mH, but the latter is too far from 10.7 MHz for the Expanded Log Detector. Interestingly, though the crystal with 22 mH was in a short can like Jerry's, as opposed to the much taller can for my 10.7 MHz and the 10.73 MHz crystals, which had 10 mH. I associate the shorter cans with computer clock crystals. Perhaps that style is intentionally made with higher Lm. It would be worth finding some crystals near 10.7 MHz in the short can to see how they measure.

7837. VGA Gain question

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-15 01:14:56 UTC
From: davidhooau
Topic: 7837 Message: 7837

Hi folks (I really mean Sam),

Sam's fine paper on his expanded log detector uses a VGA K1 value of 65dB, which implies 15dB gain when VDBS is >1.5V.

My VGA measures about well below this, and I'm puzzled where the 15dB figure comes from. I figure it should be, using very approximate figures:

> +12dB from input transformer.
> -6dB from output transformer.
> 0dB from AGC section.
> +7.6dB from VMAG scaling
> -4.8dB from output section (150ohm source into 200ohm load)
> Transformer losses and loss into R1

What am I missing (apart from the plot)?

Thanks,

davidh

David,
It would take me a while to get back into that mathematics, and the current VGA is a bit different from the original. I believe the current VGA is slightly different yet. The original paper was done in 2008, and updated in 2010. It is possible that I didn't update the values in the formula to match the new schematic. My main purpose in the math was simply to show that the overall combination maintains a log detector response.

VDBS would be near 1.5V at max input, which will be something in the 0-5 dBm range, so we don't want much gain, if any. Your list of gains/losses seems correct except I think since you count -4.8 dB for the 150 ohm source into 200 ohm load, you need to add +6 dB because the reference for calculating gain would be 50 ohms into 50 ohms, which would have 6 dB loss.

Gain for high level signals is actually less important than the point at which the VGA output saturates (with VDBS at 1.5V). Gain is more important for low level signals, and the thing to test there, rather than the amount of gain, is the level at which the response diminishes due to noise. It would be best to do that test with the noise filter in place. In operation, VDBS will never fall below about 0.4 V, so you could test low level signals with VDBS set there. The response should start curving due to noise at about -105 or -110 dBm, depending what noise filter you use.

But it is best to do testing of dynamic range with the entire unit (VGA+Filter+Log Detector) assembled. If your VGA is basically functional, and gets approximately a 50 dB gain variation over the range of the control voltage, I suggest building the remaining items and then testing them as a group. Test them by providing an input from -120 dBm to 5 dBm and plotting the MagVolts output of the log detector. For high level signals, you can check the VGA output on a scope for saturation, although as long as MagVolts is increasing significantly with increased signal level, you are OK.

I found that I actually got the best response by putting a 4-6 dB attenuator after the noise filter, which has the effect of cranking up the VGA gain a bit.

7839. PLO1&3 issues (still)

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-15 15:56:57 UTC
From: William Dillon
Topic: 7839 Message: 7839

Hi everyone,

It's been a while since I've posted. I was stuck last time with my PLO1 & PLO3 failing. I had assumed at that point that it was likely a control issue. I re-built all of my digital control wiring, taking extra care with respect to signal integrity. Now, I can verify that the digital signals are very clean. Also, using my logic analyzer, I captured signals for PLO3 and deciphered them using the lmx2326 datasheet. Again, everything seems very logical. While I was poking around with the frequency counter, I noticed that there was a very weak signal at the Fin pin on the PLL chip. It was so weak, in fact, that the counter didn't really even register it. I looked back through the message archives, and came across the conversation with Santosh in november of last year, specifically:

"The 5dBm output from the VCO goes through
* a 14dBm splitter
* the ERA33 which as a gain ranging between 19.08dBm to 17.13dBm in the 1000MHz to 2100MHz freq range (refer to spec data at 40mA and 85C)
* the 2.5dBm attenuator
So the PLO1 output will be 5 - 14 + 18 - 2.5 = 6.5dBm"

While this doesn't necessarily apply to the discussion of the PLL chip, I realized that between a 5dBm signal out of the VCO, 14dBm splitter, and some misc. loss; I'm right on the edge of the minimum input level for the PLL chip (-10dBm).

I'm wondering if this may be why my PLL chip isn't locking. For reference, I've checked this signal level using what I've constructed of the MSA so far (specifically log-detector and ADC), and compared it to the PLO2 input level. The PLO1 and PLO3 levels are about 4dB down from the PLO2 level. Does this seem like a logical conclusion? Would it be worth my time to fix my VCO's (U5) on each of these devices for better VCO output?

Thanks!
- Will

p.s. There is a small error on your website, Scotty. On the testingslim.html page there is a link to the "Testing the Integrated MSA" which is linked to "file:///C:/My%20Documents/aWebPage/trouble.html" It should probably be "trouble.html".

Low power could be the locking problem, but I'm confused about how you are determining the power level with the log detector and ADC. The log detector module is limited to relative low frequencies due to the IC itself and the transformer, so you can't accurately measure 1 GHz signals. You need the peak detector, a power meter or a way to mix the signals down to a frequency you can measure.

7841. Filter Analysis and Ripple

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-15 17:34:08 UTC
From: Sam
Topic: 7841 Message: 7841

In tweaking my amplifilter, I suddenly got a response that showed 2 dB of ripple in Filter Analysis, even though I couldn't see much ripple. It turns out that if you have a bit of ripple on one side of the peak and a bit on the other side, the entire span of what lies between them is considered ripple. So you have to apply some common sense to the ripple measurement.

Ripple can be precisely defined when you are dealing with mathematical formulas for filter response, but if you are looking at an arbitrarily wiggly response, it is hard to come up with an algorithm that always does what you want. The algorithm used by Filter Analysis is geared toward ripple on relatively flat peaks, with no additional ripple down the sides.

As a first-cut, I'm using the signal meter on my frequency counter, though that doesn't tell me anything about dBs. I had been using a difference in reading from one to the other, though I realize now that the log detector is much more likely to register a higher value for 1024 Mhz that it would for 2200 Mhz. I think I have the parts to make the peak detector, and meant to build it, but haven't yet. Maybe I'll do that now. Did you do the optional modification to raise the voltage for the VCO to 6 volts? Is that something that's a good idea anyway?

Hi,

The vco of PLO2 has a higher output, 8dbm, compared to the vco of PLO1&3 so it's normal that the levels are different. I'm using a zcomm vco thats even lower in power and have no locking problem. But If you think that the level is too low for the pll why not lower the attenuation of the 14db splitter?

Simon

I'm wondering if this may be why my PLL chip isn't locking. For reference, I've checked this signal level using what I've constructed of the MSA so far (specifically log-detector and ADC), and compared it to the PLO2 input level. The PLO1 and PLO3 levels are about 4dB down from the PLO2 level. Does this seem like a logical conclusion? Yes, I raised the supply to +6V. There doesn't seem to be any reason not to.

When you have the peak detector, the most reliable way to measure power is to cable a PLO output to the meter. If necessary, you can use a probe, but there is likely to be some loss in the probe. I used a female SMA connector with very short piece of thin coax sticking out (the coax came with the connector when I bought it on eBay). I got the center conductor sticking out a bit beyond the shield. I could measure points in the PLO by pressing the coax shield against the fencing as ground, and touching the target point with the center conductor. I even measured the VCO output directly by this method, though I'm not sure I'd recommend that. Better to touch a point downstream of an attenuator. You impose an extra 50 ohm load, so the source sees 25 rather than 50, reducing the circuit voltage to 2/3 of its unprobed value, a reduction of 3.5 dB, which you have to add back in. With a bit of experimentation, I decided that the probe itself had another dB of loss, due to the imperfect grounding. Of course, if you probe an actual output with no load attached, you don't need to add the 3.5 dB.

Sam W.

> As a first-cut, I'm using the signal meter on my frequency counter, though that doesn't tell me anything about dBs. I had been using a difference in reading from one to the other, though I realize now that the log detector is much more likely to register a higher value for 1024 Mhz that it would for 2200 Mhz. I think I have the parts to make the peak detector, and meant to build it, but haven't yet. Maybe I'll do that now. Did you do the optional modification to raise the voltage for the VCO to 6 volts? Is that something that's a good idea anyway?

The log detector module is limited to relative low frequencies due to the IC itself and the transformer, so you can't accurately measure 1 GHz signals. You need the peak detector, a power meter or a way to mix the signals down to a frequency you can measure.

Thanks for the responses so far, I have some new items on my list of things to check/try. I have one more thing to bring up before I go off for a while and apply what I've learned, and that is the contents of the control commands to PLO3. I collected these when I had the logic analyzer hooked up. I'm posting it half so that if anything stands out as way off, maybe someone will notice, and half, assuming it's normal, there will be an example of the control words in the archive... These were collected during initial power-on, and the bits are in the order that they should be assuming that the PLOs are MSB-first. The letters and numbers below the binary are the names for the registers from the datasheet, such as c1, c2, f10, etc... The meaning of each command word is according to my interpretation of the datasheet. Make sure you're using a monospace font.

Thanks,
- Will

First command sent:

```
10 11100 1000010000000
cc aaaaa bbbbbbbbbbbbb
12 12345 1234567890123
```

A counter = 00111 = 7
B counter = 100001 = 33

Second command sent:

```
11 0 0 000 0 0 0 0 0 0000 000 0 0
cc f f fff f f f f f ffff fff f f
1 1111 111 1 1
12 1 2 345 6 7 8 9 0 1234 567 8 9
```

Counter reset = 0 - Do not reset counters
Power down = 0 - Normal operation (power on)
FoLD control = 000 - Tri-state on FoLD pin
PD Polarity = 0 - CP Polarity negative
CP Tri-state = 0 - Normal operation
Fastlock enable = 0 - Disabled (not forced)
Fastlock control = 0 - No timeout counter
Timeout counter enable = 0 - Timeout counter disabled
Timeout counter value = 0000 - Timeout 3 PD cycles
Testmodes = 000 - Normal
Powerdown mode = 0 - Asynchronous power down
test mode = 0 - Normal

Third command sent:

```
00 11010000000000 0000 0
cc rrrrrrrrrrrrr tttt p
```

11111
12 12345678901234 1234 1

R counter = 1011 = 11
test mode = 0000 = normal
precision = 0 = 3 reference cycles for lock detection

Hi William,
I went back in history to find out what your original problem was, but I can locate the posts. So let's start fresh.
I noticed at one time your Master Oscillator had possible incorrect resistors at R1 and R2. I couldn't read R3. Tell me these are all correct as 33R0 (33 ohm).

The bits below say that the PLO has counters as follows:
Acounter=7
Bcounter=33
The frequency commanded would be (10.7/11)x[(32x33)+7] = 1034 MHz, approximately. For PLO 3, this would be correct.

If you are using testingslim.html page, tell me where the first failure takes place in the procedure.

Although the Log Detector has a cut-off frequency around 160 MHz, it will still measure some power at 1034 Mhz. It will be quite low, but if you compare PLO1 or PLO3 to PLO2, you should get relative readings. PLO2 will probably measure abut 4 dB higher than the other two.

By the way, every time you click "Restart", all of the modules will get re-commanded, just as if you were starting the MSA software from the beginning.
Scotty

Good point. The ROS-1500 data sheet shows +8 dBm as the general spec but the table shows almost +10 dBm at the low frequencies, so it could even be 5 dB higher than PLO1 and PLO3. If PLO1 and 3 are roughly equal and PLO2 is roughly 5 dB higher, it seems very likely that they all are at the proper level.

If you still suspect low power you could temporarily make R7=150 ohms to boost the feedback power and see if that causes locking.

Sam W.

Hi Scotty,

That's correct, my resistors on the MO were 330 ohm. I changed them some time after the photo was taken, and now I have strong, clean signals on every oscillator connection (including on the input pins the the DDS ICs themselves).

Also, the squared 10.7 Mhz signal out of the DDS is very nice and strong.

I have been looking over the datasheet carefully for the last hour or so, and I agree that the control words look nice.

The first failure is a little hard to estimate, because most of the supply voltages are a little out of spec, but nothing that concerns me too much.
However, I expect the first real failure, and subsequent failures are:

Bias voltage: 2.51 (within spec, but for reference below)
Loop balance voltage: 2.39 (far from equal to bias voltage)
VCO Control voltage: 23.1

I should mention that I have the higher-voltage option in the +20 supply, which is reason for the +23v at the VCO control pin.

I've observed exactly that, PLO2 is about +4 relative to PLO1 and 3. Exactly as expected, now that I know it's supposed to be.

I'm happy now that I can verify clean and correct digital signaling to the PLO modules, as that was a stumbling block for me last time.
Also, I still have the email from you before about changing a line of code in the basic source to enable R and N divider output. I'll try that when I get home.

From: davidhooau
Topic: 7837 Message: 7849

Thanks Sam,

I've posted a graph of my initial results in the photo section (davidh's build). This shows the same dual slope you saw, and I'm pretty happy with this as a starting point. I have yet to put a lid on the LD, so the measurements down low are probably a consequence of this.

I'll adjust the resistive divider as you suggested. I might dispense with the 2k7 on the LD SLIM to maximise the signal into the ADC unless you consider the additional filtering it provides with C13 to be important.

One more question please. Why did you use a 4-1 (Z) transformer at the AGC output instead of a 3-1?

Cheerio,

davidh

The original paper was done in 2008, and updated in 2010. It is possible that I didn't update the values in the formula to match the new schematic. My main purpose in the math was simply to show that the overall combination maintains a log detector response.
>
> VDBS would be near 1.5V at max input, which will be something in the 0-5 dBm range, so we don't want much gain, if any. Your list of gains/losses seems correct except I think since you count -4.8 dB for the 150 ohm source into 200 ohm load, you need to add +6 dB because the reference for calculating gain would be 50 ohms into 50 ohms, which would have 6 dB loss.
>
> Gain for high level signals is actually less important than the point at which the VGA output saturates (with VDBS at 1.5V). Gain is more important for low level signals, and the thing to test there, rather than the amount of gain, is the level at which the response diminishes due to noise. It would be best to do that test with the noise filter in place. In operation, VDBS will never fall below about 0.4 V, so you could test low level signals with VDBS set there. The response should start curving due to noise at about -105 or -110 dBm, depending what noise filter you use.
>
> But it is best to do testing of dynamic range with the entire unit (VGA+Filter+Log Detector) assembled. If your VGA is basically functional, and gets approximately a 50 dB gain variation over the range of the control voltage, I suggest building the remaining items and then testing them as a group. Test them by providing an input from -120 dBm to 5 dBm and plotting the MagVolts output of the log detector. For high level signals, you can check the VGA output on a scope for saturation, although as long as MagVolts is increasing

significantly with increased signal level, you are OK.

7850. RBW Switch PCB

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-16 01:53:59 UTC
From: davidhooau
Topic: 7850 Message: 7850

Folks,

Does any kind soul out there have a 2P4T filter switch PCB I could purchase? It's the last bit I need to finish my SSA, and is probably beyond my home brew PCB making skills.

Thanks,

davidh

7851. YIG PO-2

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-16 11:22:49 UTC
From: jghbeta
Topic: 7851 Message: 7851

Hi Scotty,
I am working on a YIG for PLO2. The Yig outputs 15 dBm and it is followed by a 15 dBm attenuator to limit the input to the divide by 8 prescaler (a Hittite HMC363S8G) to 0 dBm. The prescaler output (1024 MHz) is - 6 dBm. This is going to be split to go to Mxr 2 and Mxr 3. The YIG PLL feed back is taken care off at the YIG output so the splitter here is just a two way 6 dBm. This means that at the input of the MMIC amps I have -12 dBm (-6 from the prescaler output plus -6 from the splitter attenuation). Here is were I am stuck: I need +10 dBm at the mixers (an amplifier gain of 22 dBm). Any suggestions? Obviously I am concerned with introducing amplifier noise and nullifying the YIG advantage.

Jim W1JGH

David,
Don't delete that 2.7k resistor. It is critical for filtering, and also has some effect on the feedback ratio to the VGA. Speaking of which, there were several iterations of the VGA; the final one has a 10k and 27k voltage divider in the VDBS line. Does yours have that?

The 1:4 transformer was originally a mistake; I had it in my mind that the AD8330 output impedance was 180 ohms, whereas it is 150 ohms. But the 1:4 makes the voltage to the log detector a bit lower, which is a slightly good thing. It causes the log detector to increase the gain of the VGA, putting it in a range where its internal noise performance is a bit better. This same principle is why adding a 6 dB attenuator after the noise filter improves performance a bit.

Your graph flattens out at the low end almost 10 dB higher than I expected. As you say, this may have to do with lack of shielding, which might cause some low level interference. I found that my log detector had a small bump in its noise output, which went away when I put a 22 pF cap across the AD8306 output (it fits nicely across the output resistors.) So the bump was actually a feedback problem. This may have to do with the fact that I decreased R6 to 75 ohms to increase the RF output level.

But your graph also extends nicely to 10 dBm, which makes me wonder whether the whole thing isn't shifted to the right, perhaps due to the possibly low gain issue you mentioned. Maybe there is a problem with the input transformer (under-transforming). I would also check the VDBS voltage at the IC pin to see if the voltage divider is working correctly. Finally, be sure VMAG is correct.

You can actually utilize the response up to 10 dBm if you use Scotty's IF2 amp, but one of my objectives was to reduce the max power put through the filters, so it would be nice if the response could be shifted left to cover the same range but at lower power levels.

Sam W.

7853. Re: YIG PO-2

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-16 16:36:38 UTC
From: Sam
Topic: 7851 Message: 7853

Jim,
As long as you are going the fancy route with the YIG, here is a modestly spendy solution. You need isolation between the two branches of LO2, which is one purpose of the original amps. The isolation comes from the attenuation in the amp plus the reverse isolation of the MMIC. If you run two separate dividers with two separate attenuators from your YIG, you'll get a good start on isolation--at least as much as comes from the splitter off the original VCO. The phases out of the two dividers won't be the same, but due to differing line lengths the two LO2 branches are never the same phase anyway; the important thing is that they maintain whatever phase relationship they have. (Having two dividers is really no different than having PLO1 and PLO3 run by different DDSs.)

Next, an isolator on each line, such as:
http://cgi.ebay.com/Teledyne-C-1S13T-3-Circulator-950-1150MHz-<20dB-Isolat-/300429680576?pt=LH_DefaultDomain_0&hash=item45f3011fc0>

You could even put the isolators before the dividers, where a small amount of loss is irrelevant.

If you don't like the two-divider idea, then use two isolators on each line, or maybe only on the line leading to mixer 3--the extra isolator would replace the buffer amp.

Maybe the dividers themselves actually have a good amount of isolation, in which case the isolators might not be critical. That would be easy to check once you get the dividers hooked up.

Then you need an amp on each line, such as ABA-52563, to get up to LO level.

Sam W.

From: Sam
Topic: 7851 Message: 7854

Caveat: The isolator idea assumes that the prime concern with isolation is in the 1013-1150 MHz range. In that range an isolator might provide 20-40 dB of isolation. For LO1 or LO3 above that trying to leak back to the YIG, the isolator would probably provide attenuation of only 10 dB or so. Maybe add a low-pass filter like LFCN-900?

Hi David,

I still have those in stock. They are $5.00 plus $1.00 shipping. Paypal is the best payment method for me.
My Paypal account number is my e-mail address: rwfish@...

Thanks,

Bob

Sam,

Wilco on the 2k7, and yes, I have 10k/27k giving an overall P of 0.68.

May I again check the VGA levels with you?

Looking only at voltage levels, with VDBS > 1.5V:

> input xfmr: Av=4
> loss due to 3k9: Av=0.8
> VGA: Av=1
> Vmag: Av=2.4
> output resistors: Av=0.57
> output transformer: Av=0.5

This gives me an overall gain (50R to 50R) of 2.188 or 6.8dB, which is exactly what I've measured.

What am I missing?

Thanks,

davidh

>
> David,
> Don't delete that 2.7k resistor. It is critical for filtering, and also has some effect on the feedback ratio to the VGA. Speaking of which, there were several iterations of the VGA; the final one has a 10k and 27k voltage divider in the VDBS line. Does yours have that?
>
> The 1:4 transformer was originally a mistake; I had it in my mind that the AD8330 output impedance was 180 ohms, whereas it is 150 ohms. But the 1:4 makes the voltage to the log detector a bit lower, which is a slightly good thing. It causes the log detector to increase the gain of the VGA, putting it in a range where its internal noise performance is a bit better. This same principle is why adding a 6 dB attenuator after the noise filter improves performance a bit.
>
> Your graph flattens out at the low end almost 10 dB higher than I expected. As you say, this may have to do with lack of shielding, which might cause some low level interference. I found that my log detector had a small bump in its noise output, which went away when I put a 22 pF cap across the AD8306 output (it fits nicely across the output resistors.) So the bump was actually a feedback problem. This may have to do with the fact that I decreased R6 to 75 ohms to increase the RF output level.
>
> But your graph also extends nicely to 10 dBm, which makes me wonder whether the whole

thing isn't shifted to the right, perhaps due to the possibly low gain issue you mentioned. Maybe there is a problem with the input transformer (under-transforming). I would also check the VDBS voltage at the IC pin to see if the voltage divider is working correctly. Finally, be sure VMAG is correct.
>
> You can actually utilize the response up to 10 dBm if you use Scotty's IF2 amp, but one of my objectives was to reduce the max power put through the filters, so it would be nice if the response could be shifted left to cover the same range but at lower power levels.

The original paper was done in 2008, and updated in 2010. It is possible that I didn't update the values in the formula to match the new schematic. My main purpose in the math was simply to show that the overall combination maintains a log detector response.
> > >
> > > VDBS would be near 1.5V at max input, which will be something in the 0-5 dBm range, so we don't want much gain, if any. Your list of gains/losses seems correct except I think since you count -4.8 dB for the 150 ohm source into 200 ohm load, you need to add +6 dB because the reference for calculating gain would be 50 ohms into 50 ohms, which would have 6 dB loss.
> > >
> > > Gain for high level signals is actually less important than the point at which the VGA output saturates (with VDBS at 1.5V). Gain is more important for low level signals, and the thing to test there, rather than the amount of gain, is the level at which the response

diminishes due to noise. It would be best to do that test with the noise filter in place. In operation, VDBS will never fall below about 0.4 V, so you could test low level signals with VDBS set there. The response should start curving due to noise at about -105 or -110 dBm, depending what noise filter you use.
> > >
> > > But it is best to do testing of dynamic range with the entire unit (VGA+Filter+Log Detector) assembled. If your VGA is basically functional, and gets approximately a 50 dB gain variation over the range of the control voltage, I suggest building the remaining items and then testing them as a group. Test them by providing an input from -120 dBm to 5 dBm and plotting the MagVolts output of the log detector. For high level signals, you can check the VGA output on a scope for saturation, although as long as MagVolts is increasing significantly with increased signal level, you are OK.

Hi Sam,
The prescaler has two outputs at 180 degrees from each other. The only other information that I get from the dta sheet is that the reverse leakage, with both outputs terminated, is 65 dB. I am not on firm ground here, but if as you said, there is always going to be a phase diffrence anyway, I could use these two outputs without need for the splitter. Then I could follow them by a buffer, LNA or whatever to reach MXR2 and MXR3.

David,
Your numbers seem correct. What confuses me is how you can get such a good response with inputs up to 10 dBm.

Per p. 16 of the data sheet, with VMag=1.2 and a load of 200 ohms, the max voltage swing at the AD8330 output is +/-1.4V. At the transformer secondary, this would be halved to +/-0.7V. That is 7 dBm. With a gain of 6.8 dB, the AD8330 should start saturating with an input of 0.2 dBm. There would still be increased output with increased input (the output starts to square, but the fundamental content will still increase), but the response should start to flatten at 0.2 dBm input. Your response seems very linear well beyond that.

It seems odd to be worried about the circuit functioning too well at high input levels, but I wonder whether that is connected with the low end not extending as far as it should.

I'm surprised that a divider data sheet even mentions reverse leakage. If it is 65 dB, which seems phenomenal, all you would have to do is run each output through an amp (the need for two amps seems unavoidable), which will have some additional reverse isolation, probably 20-30 dB. That should put you in good shape.

It certainly would be possible to construct the YIG+divider and check the reverse isolation. You would input a strong signal to one divider output and look for it in the other divider output. If the divider is outputting 1024 MHz, you could try various frequencies from 1013 to 2013 MHz, but of course you couldn't test at exactly 1024 MHz.

Hi Jim,
On Sam's comment I went and looked at the Hittite data sheet. The 65 dB isolation spec is from either output back to input, not output A to output B. Since both outputs are separated by only the internal source resistors (probably 50 ohm) the output port to output port is probably less than 20 dB. As Sam suggested, you can test the isolation but here is a good method that is a little easier and still provide good results. Bias the input of the Hittite divider so that it has no input and does not oscillate. Each output will be either at a "0" or "1". No toggling at all. This way there is no RF power applied back into your test equipment. The actual isolation results will probably look a bit better than when the Hittite is dividing normally. But it should be within a few dB.

Even if the isolation is crummy, you can still feed each of those outputs to separate amplifiers, such as the SLIM-RFA-1, to feed Mixers 2 and 3.. Just remove the input attenuators in the SLIM-RFA for full gain.
Scotty

From: davidhooau
Topic: 7837 Message: 7861

Hi Sam,

To use an American expression, I've thrown you a curve ball.

When I plot more samples and look closely at the raw data, I'm only in the "linear" range up until 0dBm input, which is pretty close to VDBS being 1.5V.

At +5dBm I'm reading about 2dB high at the LD output, as the slope is now that of the AD8306 alone, 0.02V/dB vs. 0.013V/dB with my AGC/LD combination.

At 10dBm input limiting is taking place, I'm guessing as the AD8330 runs out of puff, and it just happens that this 10dBm sample is approximately in the same line as the data between -40 and 0dBm. If I'd gathered more samples in the first graph, this would have been much clearer. (memo to self...)

I'll adjust VMAG to get the overall AGC gain range correct (15-65dB) and check that my system now functions per your paper.

Many thanks for your help with this.

davidh

7862. Re: VGA Gain question

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-17 13:49:22 UTC
From: Sam
Topic: 7837 Message: 7862

David,
The only purpose of looking at the high end is to see whether there is some problem with the module that might also affect the low end, and we don't seem to have found any such problem. So maybe the abrupt flattening at the low end is due to the lack of shielding, as you originally suggested.

If you try adjusting VMag, you'll find that your efforts are largely defeated by the feedback loop. For example, lowering VMag lowers the VGA gain, reducing the log amp input and therefore the feedback voltage. The lower feedback voltage increases the VGA gain, partially cancelling the effect of the original lowering of VMag. You get a similar effect if you adjust the feedback ratio.

I suggest that you put the fencing and lid on the log detector, which is where shielding is the most important, and then check the low end response.

I've been assuming you have the noise filter in place. Is it the 500 kHz filter? Perhaps the only difference between your response and that in my paper is the noise filter width. I used 150 kHz. In my MSA I am using 500 kHz. I did not directly test the response of the Expanded Log Detector with that wider filter, but it did not seem to affect the lowest detectable signal level at the MSA input. Possibly the Expanded Log Detector's low end response would be extended with a narrower filter, but that extra range is not reachable with my narrowest RBW filter, which is now 2 kHz. Maybe a narrower noise filter would be useful when I install my 600 kHz amplifilter. If so, I'll have to reconsider using the switchable noise filter, which would allow a wide noise filter for all RBW's except the narrowest one, where a much narrower one would kick in.

As a rough calculation, if you input to the MSA a signal of -115 dBm and have losses of 20 dB by the time you reach the IF2 amp, the signal is -135 dBm at that point, -107 dBm at the output of the 28 dB amp, and perhaps -110 dBm at the output of the RBW filter. At that point the signal will be accompanied by noise from the amp (say, -174 dBm/Hz plus 4 created by the amp plus 28 due to amplification) equal to -142 dBm/Hz. With a 2 kHz RBW filter with 3 dB loss, that is -142+36-3=-109 dBm of noise, accompanying the -110 dBm signal. The signal would still be discernible, but there would any point in the Expanded Log Detector maintaining a strong response below the -109 dBm noise level, which is about where yours (and maybe mine) peters out. A narrower noise filter would therefore not be of much benefit. With a 600 Hz RBW filter, the noise level would be reduced by 5 dB, so a narrower noise filter might increase the low end range by 5 dB. Maybe not worth the effort.

(Note that a detector that dies below -110 dBm can still detect a -112 dBm signal if the signal is accompanied by enough noise to push the total signal+noise over -110 dBm. The noise actually provides some benefit! The detector needs a range that extends down to the noise level, but the actual detectable signal will extend below the detector's nominal range.)

That is 7 dBm. With a gain of 6.8 dB, the AD8330 should start saturating with an input of 0.2 dBm. There would still be increased output with increased input (the output starts to square, but the fundamental content will still increase), but the response should start to flatten at 0.2 dBm input. Your response seems very linear well beyond that.

Hi Jim (and others who are following Jim's YTO plan),
  I thought I would add an addition to my comment about adding amplifiers. If you have room on your Hittite divider board, you could add the amplifiers there. For example, if each Hittite output has a circuit trace going to an output connector:
Cut out about 3/16" of the trace and install the MMIC amplifier in the center of the void. Solder the side ground leads of the MMIC to the pwb grounds on each side of the original trace. It there is no good top ground, drill some holes through the board and bend and insert the MMIC ground leads through the board. Then add two 100 pfd chip caps in series, one on the input and one on the output of the MMIC. Use the Vcc of the Hittite board to power the MMIC output pin, through a dropping resistor and a choke (20 nH to 100 nH). With -6 dBm supplying each MMIC, full output power of +13 dBm (compression level) should result. If there is still room on the Hittite board, you can add a 3 dB resistive pi attenuator. If not, add the attenuator off-board and in line to each Mixer. Or, you could just increase the attenuator in each Mixer by 3 dB. The -6 dB number is Hittite's typical spec. It could be as low as -9 dBm. If so, no output attenuator is necessary, as
the MMIC output would be about +10 dBm (19 dB gain).
  This would add about 76 ma of current consumption for your Hittite board. Make sure its voltage regulator can handle the addition.
Scotty

Hi Jim,
On Sam's comment I went and looked at the Hittite data sheet. The 65 dB isolation spec is from either output back to input, not output A to output B. Since both outputs are separated by only the internal source resistors (probably 50 ohm) the output port to output port is probably less than 20 dB. As Sam suggested, you can test the isolation but here is a good method that is a little easier and still provide good results. Bias the input of the Hittite divider so that it has no input and does not oscillate. Each output will be either at a "0" or "1". No toggling at all. This way there is no RF power applied back into your test equipment. The actual isolation results will probably look a bit better than when the Hittite is dividing normally. But it should be within a few dB.

 Even if the isolation is crummy, you can still feed each of those
outputs to separate amplifiers, such as the SLIM-RFA-1, to feed Mixers 2 and 3.. Just remove the input attenuators in the SLIM-RFA for full gain.
Scotty

I'm surprised that a divider data sheet even mentions reverse leakage. If it is 65 dB, which seems phenomenal, all you would have to do is run each output through an amp (the need for two amps seems unavoidable), which will have some additional reverse isolation, probably 20-30 dB. That should put you in good shape.

It certainly would be possible to construct the YIG+divider and check the reverse isolation. You would input a strong signal to one divider output and look for it in the other divider output. If the divider is outputting 1024 MHz, you could try various frequencies from 1013 to 2013 MHz, but of course you couldn't test at exactly 1024 MHz.

Analog's adl5513 amp has a noise figure of 0.8 against 2.8+ with the MMIC. the ADL is not solder friendly but other than that do you think is worth the change?

From: davidhooau
Topic: 7837 Message: 7865

Hi Sam,

Yes, I'm using the 500kHz noise filter we were tuning a few days ago.

I've posted a slightly clearer graph, including the LD alone, with some additional samples to clarify things. Now, at the upper limit between 0dBm and 5dBm, you can see the slope increase as we run out of AGC range, and then the LD run out of range, making the 10dBm sample look better than it really is.

For reference, the minimum AGC gain is now 7dB, the NF is 500kHz wide with an insertion loss of 4dB. The net division ratio from LD to VDBS is 0.68 and the ADC is connected per your current drawing (between the 2k7 and 10k-27k on the AGC unit).

I'm going to have to put testing off for a couple of weeks, as I have a road trip for work.

Cheers,

davidh

>
> David,
> The only purpose of looking at the high end is to see whether there is some problem with the module that might also affect the low end, and we don't seem to have found any such problem. So maybe the abrupt flattening at the low end is due to the lack of shielding, as you originally suggested.
>
> If you try adjusting VMag, you'll find that your efforts are largely defeated by the feedback loop. For example, lowering VMag lowers the VGA gain, reducing the log amp input and therefore the feedback voltage. The lower feedback voltage increases the VGA gain, partially cancelling the effect of the original lowering of VMag. You get a similar effect if you adjust the feedback ratio.
>
> I suggest that you put the fencing and lid on the log detector, which is where shielding is the most important, and then check the low end response.
>
> I've been assuming you have the noise filter in place. Is it the 500 kHz filter? Perhaps the only difference between your response and that in my paper is the noise filter width. I used 150 kHz. In my MSA I am using 500 kHz. I did not directly test the response of the Expanded Log Detector with that wider filter, but it did not seem to affect the lowest detectable signal level at the MSA input. Possibly the Expanded Log Detector's low end response would be extended with a narrower filter, but that extra range is not reachable with my narrowest RBW filter, which is now 2 kHz. Maybe a narrower noise filter would be useful when I install my 600 kHz amplifilter. If so, I'll have to reconsider using the switchable noise filter, which would allow a wide noise filter for all RBW's except the narrowest one, where a much narrower one would kick in.
>

> As a rough calculation, if you input to the MSA a signal of -115 dBm and have losses of 20 dB by the time you reach the IF2 amp, the signal is -135 dBm at that point, -107 dBm at the output of the 28 dB amp, and perhaps -110 dBm at the output of the RBW filter. At that point the signal will be accompanied by noise from the amp (say, -174 dBm/Hz plus 4 created by the amp plus 28 due to amplification) equal to -142 dBm/Hz. With a 2 kHz RBW filter with 3 dB loss, that is -142+36-3=-109 dBm of noise, accompanying the -110 dBm signal. The signal would still be discernible, but there would any point in the Expanded Log Detector maintaining a strong response below the -109 dBm noise level, which is about where yours (and maybe mine) peters out. A narrower noise filter would therefore not be of much benefit. With a 600 Hz RBW filter, the noise level would be reduced by 5 dB, so a narrower noise filter might increase the low end range by 5 dB. Maybe not worth the effort.
>
> (Note that a detector that dies below -110 dBm can still detect a -112 dBm signal if the signal is accompanied by enough noise to push the total signal+noise over -110 dBm. The noise actually provides some benefit! The detector needs a range that extends down to the noise level, but the actual detectable signal will extend below the detector's nominal range.)

Scotty,

Looking at the demo boards of some of the low noise amplifiers I see two things:
1. Rogers materials with fairly consistent dimensional and dielectric properties for the boards which determine the accuracy of trace dimensions
2. The components are size 402 or 605. Now the wave length of a 1GHz signal is about 12" so are these tiny components really necessary? 605 are a pain but doable but 402 are beyond humans (unless armed with binocular microscopes and very steady hands).

What's your take on this?

Jim,
If you can solder that IC, 0402 components should be no problem! Maybe all they are trying to achieve with 0402 components is to be able to get all of them near the tiny IC. There is an amazing number of components on the input side.

I think the advantage of Rogers in this context is that (1) vias to bottom ground plane are short (low inductance) and (2) 50-ohm transmission lines are skinny, making it easier to attach the input and output to those tiny little leads without a huge discontinuity. These might be factors that affect gain, but I don't see that they would affect noise figure. But I have used Avago's ABA-52563 on ExpressPCB FR-4 and got good gain at 1-2 GHz.

Sam W.

Hi Sam,

Yes, I'm using the 500kHz noise filter we were tuning a few days ago.

I've posted a slightly clearer graph, including the LD alone, with some additional samples to clarify things. Now, at the upper limit between 0dBm and 5dBm, you can see the slope increase as we run out of AGC range, and then the LD run out of range, making the 10dBm sample look better than it really is.

For reference, the minimum AGC gain is now 7dB, the NF is 500kHz wide with an insertion loss of 4dB. The net division ratio from LD to VDBS is 0.68 and the ADC is connected per your current drawing (between the 2k7 and 10k-27k on the AGC unit).

I'm going to have to put testing off for a couple of weeks, as I have a road trip for work.

Cheers,

davidh

>

> David,

> The only purpose of looking at the high end is to see whether there is some problem with the module that might also affect the low end, and we don't seem to have found any such problem. So maybe the abrupt flattening at the low end is due to the lack of shielding, as you originally suggested.

>

> If you try adjusting VMag, you'll find that your efforts are largely defeated by the feedback loop. For example, lowering VMag lowers the VGA gain, reducing the log amp input and therefore the feedback voltage. The lower feedback voltage increases the VGA gain, partially cancelling the effect of the original lowering of VMag. You get a similar effect if you adjust the feedback ratio.

>

> I suggest that you put the fencing and lid on the log detector, which is where shielding is the most important, and then check the low end response.

>

> I've been assuming you have the noise filter in place. Is it the 500 kHz filter? Perhaps the only difference between your response and that in my paper is the noise filter width. I used 150 kHz. In my MSA I am using 500 kHz. I did not directly test the response of the Expanded Log Detector with that wider filter, but it did not seem to affect the lowest detectable signal level at the MSA input. Possibly the Expanded Log Detector's low end response would be extended with a narrower filter, but that extra range is not reachable with my narrowest RBW filter, which is now 2 kHz. Maybe a narrower noise filter would be useful when I install my 600 kHz amplifilter. If so, I'll have to reconsider using the switchable noise filter, which would allow a wide noise filter for all RBW's except the narrowest one, where a much narrower one would kick in.

>

> As a rough calculation, if you input to the MSA a signal of -115 dBm and have losses of 20 dB by the time you reach the IF2 amp, the signal is -135 dBm at that point, -107 dBm at the output of the 28 dB amp, and perhaps -110 dBm at the output of the RBW filter. At that point the signal will be accompanied by noise from the amp (say, -174 dBm/Hz plus 4 created by the amp plus 28 due to amplification) equal to -142 dBm/Hz. With a 2 kHz RBW filter with 3 dB loss, that is -142+36-3=-109 dBm of noise, accompanying the -110 dBm signal. The signal would still be discernible, but there would any point in the Expanded Log Detector maintaining a strong response below the -109 dBm noise level, which is about where yours (and maybe mine) peters out. A narrower noise filter would therefore not be of much benefit. With a 600 Hz RBW filter, the noise level would be reduced by 5 dB, so a narrower noise filter might increase the low end range by 5 dB. Maybe not worth
the effort.

>

> (Note that a detector that dies below -110 dBm can still detect a -112 dBm signal if the signal is accompanied by enough noise to push the total signal+noise over -110 dBm. The noise actually provides some benefit! The detector needs a range that extends down to the noise level, but the actual detectable signal will extend below the detector's nominal range.)

> > >

> > > Per p. 16 of the data sheet, with VMag=1.2 and a load of 200 ohms, the max voltage swing at the AD8330 output is +/-1.4V. At the transformer secondary, this would be halved to +/-0.7V. That is 7 dBm. With a gain of 6.8 dB, the AD8330 should start saturating with an input of 0.2 dBm. There would still be increased output with increased input (the output starts to square, but the fundamental content will still increase), but the response should start to flatten at 0.2 dBm input. Your response seems very linear well beyond that.

Hi Jim,
Rogers material is a highly controlled Er material. Fantastic stuff. And really expensive. And I don't suggest using it for home made boards that need to be put in the kitchen oven for solder reflow. Just a little too much heat will break down the board and create gasses that are deadly. Probably not enough from a 4 inch board, but still I warn people about that.

Scotty,

Looking at the demo boards of some of the low noise amplifiers I see two things:
1. Rogers materials with fairly consistent dimensional and dielectric properties for the boards which determine the accuracy of trace dimensions
2. The components are size 402 or 605. Now the wave length of a 1GHz signal is about 12" so are these tiny components really necessary? 605 are a pain but doable but 402 are beyond humans (unless armed with binocular microscopes and very steady hands).

What's your take on this?

Jim

Hi Jim (and others who are following Jim's YTO plan),
  I thought I would add an addition to my comment about adding amplifiers. If you have room on your Hittite divider board, you could add the amplifiers there. For example, if each

Hittite output has a circuit trace going to an output connector:

Cut out about 3/16" of the trace and install the MMIC amplifier in the center of the void. Solder the side ground leads of the MMIC to the pwb grounds on each side of the original trace. It there is no good top ground, drill some holes through the board and bend and insert the MMIC ground leads through the board. Then add two 100 pfd chip caps in series, one on the input and one on the output of the MMIC. Use the Vcc of the Hittite board to power the MMIC output pin, through a dropping resistor and a choke (20 nH to 100 nH). With -6 dBm supplying each MMIC, full output power of +13 dBm (compression level) should result. If there is still room on the Hittite board, you can add a 3 dB resistive pi attenuator. If not, add the attenuator off-board and in line to each Mixer. Or, you could just increase the attenuator in each Mixer by 3 dB. The -6 dB number is Hittite's typical spec. It could be as low as -9 dBm. If so, no output attenuator is necessary, as
the MMIC output would be about +10 dBm (19 dB gain).

This would add about 76 ma of current consumption for your Hittite board. Make sure its voltage regulator can handle the addition.

Hi Jim,
On Sam's comment I went and looked at the Hittite data sheet. The 65 dB isolation spec is from either output back to input, not output A to output B. Since both outputs are separated by only the internal source resistors (probably 50 ohm) the output port to output port is probably less than 20 dB. As Sam suggested, you can test the isolation but here is a good method that is a little easier and still provide good results. Bias the input of the Hittite divider so that it has no input and does not oscillate. Each output will be either at a "0" or "1". No toggling at all. This way there is no RF power applied back into your test equipment. The actual isolation results will probably look a bit better than when the Hittite is dividing normally. But it should be within a few dB.

Even if the isolation is crummy, you can still feed each of those outputs to separate amplifiers, such as the SLIM-RFA-1, to feed Mixers 2 and 3.. Just remove the input attenuators in the SLIM-RFA for full gain.

I'm surprised that a divider data sheet even mentions reverse leakage. If it is 65 dB, which seems phenomenal, all you would have to do is run each output through an amp (the need for two amps seems unavoidable), which will have some additional reverse isolation,

probably 20-30 dB. That should put you in good shape.

It certainly would be possible to construct the YIG+divider and check the reverse isolation. You would input a strong signal to one divider output and look for it in the other divider output. If the divider is outputting 1024 MHz, you could try various frequencies from 1013 to 2013 MHz, but of course you couldn't test at exactly 1024 MHz.

Hi Jim,
 A super low noise figure amplifier is necessary for amplifying signals that are close to the noise floor. The output of your Hittite is nowhere close to the noise floor and would not be justified. Unless they are really cheap and you have a junk box full of them.

Hi Jim,
On Sam's comment I went and looked at the Hittite data sheet. The 65 dB isolation spec is from either output back to input, not output A to output B. Since both outputs are separated by only the internal source resistors (probably 50 ohm) the output port to output port is probably less than 20 dB. As Sam suggested, you can test the isolation but here is a good method that is a little easier and still provide good results. Bias the input of the Hittite divider so that it has no input and does not oscillate. Each output will be either at a "0" or "1". No toggling at all. This way there is no RF power applied back into your test equipment. The actual isolation results will probably look a bit better than when the Hittite is dividing normally. But it should be within a few dB.

Even if the isolation is crummy, you can still
feed each of those
outputs to separate amplifiers, such as the SLIM-RFA-1, to feed Mixers 2 and 3.. Just remove the input attenuators in the SLIM-RFA for full gain.
Scotty

I'm surprised that a divider data sheet even mentions reverse leakage. If it is 65 dB, which seems phenomenal, all you would have to do is run each output through an amp (the need for two amps seems unavoidable), which will have some additional reverse isolation, probably 20-30 dB. That should put you in good shape.

It certainly would be possible to construct the YIG+divider and check the reverse isolation. You would input a strong signal to one divider output and look for it in the other divider output. If the divider is outputting 1024 MHz, you could try various frequencies from 1013 to 2013 MHz, but of course you couldn't test at exactly 1024 MHz.

7872. Parts List for Recent Group SLIMs

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-18 10:51:57 UTC
From: lh1907
Topic: 7872 Message: 7872

Are the parts list (PL) for any of the following SLIMs located anywhere?
Cal Source,
Leveler,
Active Bridge,
Buffer Amp,
Switched Attenuator,
Fixed Attenuator,
IF2 PreAmp (Pre RBW - Filter Amp),
VGA,
Noise Filter, and
AGC.

Switched Attenuator, and Fixed Attenuator PLs are straight forward. Have printed the ExpressPCB SCH/PCB files for all and if PLs are not available, I plan on starting with schematic and using PCB geometry to determine pkg size of schematic parts (i.e., which IC pkg, which SMT size - 1205, 805, etc). Getting ready to build an order on DigiKey and Mouser sites.

Larry, W2HHV

Those are all my boards, and I never do parts lists--it's one more thing to maintain. I rely on the schematics. For ICs, I mark the package type on the schematic, except possibly when there is only one package--like 78L05. All caps and resistors are size 0805 unless otherwise stated; inductors occasionally allow for bigger sizes but small ones will fit too. If in doubt, double-click on the component on the PCB layout in ExpressPCB and it will show the package type.

For caps, resistors and inductors any manufacturer will do unless a specific part number is stated. For ferrites the specific part number is always stated, since that is the only way to specify the frequency range, but another ferrite with similar range is fine. 5% resistors are generally fine unless the schematic calls for higher precision, but if you are ordering them you might as well get 1% instead of 5%. (I use 5% resistors from a Digi-Key kit, but refill with 1% when a value runs low.) For caps, use NP0 when available in that size (up to 1 nF or so).

For TI parts and 0.1% resistors, go with Mouser--better availability and price.

Sam,

Does section 7.9 (Q Measurement of LC Resonator) on Pg 7.36 of Experimental Methods of RF Design shed any light on which approach to take?

I would say that it is the same as for a low pass where the passing band is counted at the 3 dB from the bottom

7876. Re: Q of notch filter

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-18 19:09:30 UTC
From: Sam
Topic: 7818 Message: 7876

I don't have Experimental Methods readily available, but here is the conclusion I came to after considerable research. The Q of a complete filter circuit--say, 50 ohm source and load, with a series LC to ground in the middle--is based on the bandwidth between the 3 dB points at the top. That is also the loaded Q (QL) of the LC circuit. The parallel combination of source and load become the series resistance of the LC circuit (along with any intrinsic resistance). Big source and load means small QL. While Q stands for Quality Factor, it judges quality solely by the width of the top of the response, whether bandpass or bandstop, and has nothing to do with what happens at the bottom.

In reality you may be more interested in the depth of a notch (or in the height of a peak) than in the "quality" measured by QL. If you determine bandwidth from the 3 dB points at the bottom of a notch (i.e. 3 dB up from the bottom), and calculate Q=bandwidth/frequency, the "Q" value you get is a useful number but is not the loaded Q of the LC circuit. If the source and load are large (compared to the intrinsic LC resistance), this bottom Q will approximate the unloaded Q (Qu) of the LC circuit. This is interesting because the large source and load with a series LC circuit actually constitute a heavy load on the circuit, and will result in a wide bandwidth at the top, and small QL.

If the source and load are not large, the "Q" you calculate at the bottom will have a fairly complicated relationship to the Qu of the LC circuit.

If you are ultimately trying to determine the Q of an inductor with these measurements (and are assuming C is very high Q), you can do it using either the top 3 dB points (in which case it is best to have a small source and load) or the bottom 3 dB points (in which case large source and load is better). It's just a question of what formula you apply to the results, and for this purpose it is easiest to use the bottom 3 dB points, if the source and load are large. But the true QL of the circuit is the one measured at the top.

Sam W.

7877. HF306 relay

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-18 23:05:49 UTC
From: Sam
Topic: 7877 Message: 7877

I finally received my HF306 relays from DigiKey. Jim's latest board included a transmit/receive board that contains an active bridge, buffer amp, and HF306 relay. It's 12V, single coil, non-latching, 75 ohms but works as low as 9V and for this purpose the 75 ohm impedance is irrelevant. If anyone wants to get this relay, DigiKey now has a couple thousand.

I originally ordered it from Futurelec, but the got an email saying their reels of HF06 were on metal tape, so they decided they could not cut them apart. (What kind of metal is it, anyway?)

Sam W.

Hi Sam,
I makes sense that the shorter crystals have a higher Lm, since being smaller their Cm will be smaller too. The product of Lm times Cm determines the series resonant frequency, if one goes down the other must go up for the same frequency. It is pure math.

Jim

I once took apart one of the big can crystals, and there was almost nothing inside. Two leads leading to a tiny piece of crystal that was located about half way up the can. I think it would have fit into a small can. But you may be right, the small cans may have even smaller crystals.

Also, the higher the frequency, the thinner the crystal (for similar cut
and as long as they are not overtoned) and the Lm will go down. I just
tested some 11 MHz and 20 Mhz and their Lms are around 6 and 4 respectively.
I am on a holding pattern waiting for Express PCB and Digikey for YIG stuff
and the separate Mxr 3 amplifiers. I modified the layout of the later so
that i could get two of them in the 3.8x2.5 board (the rest of the space is
occupied by the Yig interfaace).. I will use a 3/4" copper bushing as a
holder/ shield. Since I am getting 6 amp boards from ExpressPCB I have two
extra ones that you are welcome to have if interested.

From: lh1907
Topic: 7872 Message: 7881

I'm almost finished generating the Mouser/DigiKey orders. A few comments:

1. Switch Noise Filter F1 (SFVLF10M7LF00-B0) BW specs are fn±25kHz min. Schematic specifies 75 kHz BW. Largest BW RBW filter I plan on using thru this signal path is 30 kHz, so 50 kHz should be wide enough.
Mouser's comment against this part is:
Factory Lead-Time: 12 Weeks Manufacturing delays have been reported on this product. Qty 498 in stock and 500 on order.

2. MBRX0540 power polarity protection diode not in stock. Substituted ZHCS400TA Schottky diode part (40 v Vr, 0.4 amp If, 6.7 amp current surge).

And a few questions:

1. Is there any recommended max ESR for solid tantalums? ESR for tantalums on current order are 3.4 ohms (4.7 uF), 4 ohms (10 uF), and 16 ohm (1.0 uF).

2. What are the recommended LPF 3 dB frequency for LFCN-575D filters on MSA/TG Front End Amplifiers for MSA applications. I plan on using a 100 MHz 3 dB frequency initially while these amplifiers are being used with Active Reflection Bridge(ARB). After MSA build/test, the MSA VNA will replace ARB.

3. Since some 805 size SMD resistors are 1/10 watt (rather than 1/8 watt) is this lower power rating acceptable.

4. Is the 5 volt LDO used on Active Reflection Bridge? Schematic shows 6 volts but a comment in Active Reflection Bridge pdf file (page 8) recommends 5 volt LDO.

5. Even though the Cal Source references a 1 MHz source (2 MHz osc), I though I saw some e-mail posting in MSA Group which recommended a higher source frequency (4 MHz?). Low frequency for constant differential phase through stepped attenuators and minimizing waveform edge ringing induced amplitude error but not too low for whatever reason??

>
> Those are all my boards, and I never do parts lists--it's one more thing to maintain. I rely on the schematics. For ICs, I mark the package type on the schematic, except possibly when there is only one package--like 78L05. All caps and resistors are size 0805 unless otherwise stated; inductors occasionally allow for bigger sizes but small ones will fit too. If in doubt, double-click on the component on the PCB layout in ExpressPCB and it will show the package type.
>
> For caps, resistors and inductors any manufacturer will do unless a specific part number is stated. For ferrites the specific part number is always stated, since that is the only way to specify the frequency range, but another ferrite with similar range is fine. 5%

resistors are generally fine unless the schematic calls for higher precision, but if you are ordering them you might as well get 1% instead of 5%. (I use 5% resistors from a Digi-Key kit, but refill with 1% when a value runs low.) For caps, use NP0 when available in that size (up to 1 nF or so).

Have printed the ExpressPCB SCH/PCB files for all and if PLs are not available, I plan on starting with schematic and using PCB geometry to determine pkg size of schematic parts (i.e., which IC pkg, which SMT size - 1205, 805, etc). Getting ready to build an order on DigiKey and Mouser sites.

7882. Cavity filter tuning

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-22 15:06:15 UTC
From: b767_fan
Topic: 7882 Message: 7882

I had initially tuned my cavity filter using a VNA a few months ago. Everything was as expected, and I was able to easily achieve 70dB of rejection. Now I went back to retune prior to putting together the entire VNA, and I only have about 45dB of rejection at the max, no matter how many combinations of screw lengths I tried.

I'm unsure what might have changed. I replaced the bolts with shorter ones for space savings, but I doubt this would affect anything. Could some dust inside affect it, or perhaps the cables on the outside are a bit damaged? The one does look a bit stressed on the outside, but I'd have to take the whole thing apart to replace it.

That ceramic filter is listed in Digi-Key as 25 kHz, which I couldn't believe, so I ordered a couple and tried them. They are actually 75 kHz. I don't think you need to use this filter with any RBW filter broader than 7.5 kHz, but you could try it out. (Even though the bandwidth seems sufficient for a 30 kHz RBW, the center frequency of the ceramic may be off-kilter.)

The original diodes are never in stock any more. There are many substitutes; yours sounds good. The diode voltage drop has some effect on the +20V supply, but any Schottky likely has low drop at such low currents.

The original 10 uF tantalums were cheap and relatively low ESR (1 ohm or less, I believe). I would use ceramics rather than a tantalum with ESR over 1 ohm. Where are the 4.7uF and 1 uF tantalums used?

The main objective of the LFCN filters is to zap signals over 1 GHz. The 575 has a cutoff far above the Active Bridge range so you could use a lower cutoff LFCN, but be sure it maintains decent attenuation in the 1-3 GHz range.

1/10 watt 0805 resistors are fine. I believe that anywhere power is at all an issue, larger sizes are specified, so we never come close to a resistor's max power.

The Active Bridge uses a 78L05 or 78L06, not an LDO. The 5V version is best unless you have a use in mind that requires lowest distortion with high level drive. I used the 6V version when I tested the harmonic level for possible use with the N2PK VNA. (The harmonics were fine.)

The Cal Source was originally intended to use a 2 MHz oscillator for 1 MHz output. Then I realized that the MSA zero-response (the hump around zero with no input) in VNA modes does not disappear sufficiently by 1 MHz, so it interferes with low level calibration. Even at 2 MHz, it will interfere with low level phase calibration. But if you use Scotty's optional buffer amp on the LO3 line to Mixer 3, you will zap the zero response enough that 2 MHz should work well for calibration, and even 1 MHz will be fine down to at least -80 dBm. 2 MHz should create no issues with the Switched Attenuator, except this minor issue: when you attach another attenuator to get more than the Switched Attenuator's max (57.5 dB), you will change the length of the signal path, which can affect phase calibration. If you add 2" of extra length, the effect is 0.15 degree or so. So you may want to start with a 0 dB attenuator in place (such as a barrel connector attached to a bullet) and then replace that when you add a real attenuator. If your extra attenuator is very short, all this may not matter.

What insertion loss are you getting? I would expect that if there is some type of damage, or a bad cable, the insertion loss would go up dramatically. Unless perhaps you have leaky input and output cables that cross each other.

7885. Re: Parts List for Recent Group SLIMs

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-22 17:43:16 UTC
From: lh1907
Topic: 7872 Message: 7885

My take away and comments/questions to two points of Sam's previous message (#7883) reply.

1. Capacitor Types:

The original 10 uF tantalums were cheap and relatively low ESR (1 ohm or less, I believe). I would use ceramics rather than a tantalum with ESR over 1 ohm. Where are the 4.7uF and 1 uF tantalums used?

The where used for the low freq bypass caps are:
SL, ARB, BA, VGA, and SNF for 1 uF,
SL, CS, ARB, BA, and VGA for 4.7 uF, and
SL for 10 uF/16v.
The "Where Used" Legend is SL - Source Leveler, CS - Cal Source, ARB - Active Reflection Bridge, BA - Buffer Amps, VGA - Variable Gain Amp, and SNF - Switched Noise Filter.

Replaced all the tantalum capacitors (1 to 10 uF value range) on order with ceramic. In selecting part options on DigiKey drop down choices, specified Low ESR in application drop down. Upshot in all cases Y5V capacitor type.
Only value, voltage, and part size (805) were specified for RF bypass caps (.001 to .1 uF). Part selected on price was X7R capacitor type in all cases. Did notice Y5V type lower in list at higher price. Is this an ESR issue? Should I change all these caps to Y5V capacitor type?

2. Optimum Cal Source Frequency:

2 MHz Cal Source frequency should create no issues with the Switched Attenuator, except this minor issue: when you attach another attenuator to get more than the Switched Attenuator's max (57.5 dB), you will change the length of the signal path, which can affect phase calibration. If you add 2" of extra length, the effect is 0.15 degree or so. So you may want to start with a 0 dB attenuator in place (such as a barrel connector attached to a bullet) and then replace that when you add a real attenuator. If your extra attenuator is very short, all this may not matter.

Looks like 2 MHz source freq is sweat spot. Changed Epson SG-615P osc part freq to 4 MHz. If path calibration is run using two Switched Attenuators, will this avoid the differential phase bias at low signal levels? I plan on building three Switched Attenuators.
Hopefully, I'll remember to put the optional buffer amp on the LO3 line to Mixer 3. Will this avoid the zero response problem down the MSA noise floor?

Are the new screws exactly the same material as the originals ?? Try the old ones to see if it restores the figures. Did you see the results you quoted when connected to the MSA or just when testing with the VNA. The VNA impedance will be different to the MSA so that may affect the results.

About 15dB, whereas before it was around 8.

I should have added this to my "cutsie" reply:
 The top tuning screws' function is to provide a teeny tiny amount of "end capacitance" to the center stubs. This electrically lengthens the stubs, which lower the resonant frequency. The material (aluminum, steel, brass) makes very little difference in the Q of the filter. The exposed length of screw outside of the top plate makes no difference at all.
 If your insertion loss went from -8 dB to -15 dB, I would suggest that something mechanical has happened. Perhaps:
1. one of your hairpins has lost its contact, cracked solder joint.
2. one of the stubs has lost its solder joint on the bottom plate (a crack)
3. It really did get dropped and one or more of the stubs has been bent. To check, remove the tuning screws and look through the bottom of each stub. The screw hole should line up with the center of the stub.
4. Do not mess with your wife unless #3 held true.

Are the new screws exactly the same material as the originals ?? Try the old

ones to see if it restores the figures. Did you see the results you quoted

when connected to the MSA or just when testing with the VNA. The VNA

impedance will be different to the MSA so that may affect the results.

Geoff

From: Sam
Topic: 7872 Message: 7890

X7R or X5R ceramics are great. Y5V are terrible; I don't know why they are more expensive. I didn't recall specifying tantalums in all those places. Ceramics are usually lower ESR, but are microphonic, and can generate voltages in the mV range if you tap the module. Normally that is an issue only with large value caps in a circuit with very high gain, but I have sometimes specified tantalums just to be safe. As a practical matter, though, for all these modules ceramics are fine. I suspect you will not be tapping the Cal Source while calibrating. If you were planning to use the Active Bridge or Buffer Amps at frequencies below 100 kHz, though, tantalum caps might have some benefit (due to the low frequency and possibly low signal levels involved).

Yes, using two switched attenuators would eliminate any issue over changing the signal path length when swapping attenuators. (There are still small changes when flipping switches, but very minor.) If you build a second one you could just populate it with 10 or 20 dB attenuators, unless you need finer resolution for other purposes.

A side note on using the switched attenuator. Phase accuracy makes it imperative that the attenuator have 50 ohm input and output impedance (high return loss) to avoid reflections that change when the settings change. It does have high return loss in the low MHz range, but terrible return loss in the 1 GHz range. LO1 signals leaking through Mixer 1 and coming out of the MSA input, reflecting off the attenuator, and then re-entering Mixer 1, can significantly affect phase measurements (and can affect dBm measurement by a few tenths of a dB). You therefore should include a low-pass filter on the MSA input when doing phase calibration. Such a filter is doubly effective, in that if it attenuates 1 GHz by 30 dB it will attenuate LO1 on the way out and attenuate any reflections on their way back in, for a total attenuation of 60 dB (or even more, since the reflections will probably not be 100%).

You can test this high-frequency reflection problem by measuring a signal with and without the lowpass filter. You would think the filter would simply reduce the dBm level due to insertion loss. In my case it actually increases the measured level by 0.2 dB by reflecting LO1 back inside. Note that reflecting LO1 is not a problem as long as the amount of reflection is fixed, and does not vary with different signal sources. The lowpass filter accomplishes that fixed reflection.

> >
> > The Active Bridge uses a 78L05 or 78L06, not an LDO. The 5V version is best unless you have a use in mind that requires lowest distortion with high level drive. I used the 6V version when I tested the harmonic level for possible use with the N2PK VNA. (The harmonics were fine.)
> >
> > The Cal Source was originally intended to use a 2 MHz oscillator for 1 MHz output. Then I realized that the MSA zero-response (the hump around zero with no input) in VNA modes does not disappear sufficiently by 1 MHz, so it interferes with low level calibration. Even at 2 MHz, it will interfere with low level phase calibration. But if you use Scotty's optional buffer amp on the LO3 line to Mixer 3, you will zap the zero response enough that 2 MHz should work well for calibration, and even 1 MHz will be fine down to at least -80 dBm. 2 MHz should create no issues with the Switched Attenuator, except this minor issue: when you attach another attenuator to get more than the Switched Attenuator's max (57.5 dB), you will change the length of the signal path, which can affect phase calibration. If you add 2" of extra length, the effect is 0.15 degree or so. So you may want to start with a 0 dB attenuator in place (such as a barrel connector attached to a bullet) and then replace that when you add a real attenuator. If your extra attenuator is very short, all this may not matter.

Examining it carefully, I see that two solder joints on the bottom plate are definitely loose and no longer making contact. Could that alone cause the issue? I actually made a typo there, the insertion loss is 50dB...pretty severe.

If the solder joints in question are the hairpins or stubs, yes. These are high current points in the filter and depend on low impedance solder connections.

Topic: 7882 Message: 7893

One (dumb?) question about the input/output coupling loops.

Instead of being grounded on the base plate would it be al right to ground them on the tube wall (about .7" high) and then make the exit of the coax through a couple of holes in the base plate?

I see you mention high currents in that area and this may be a problem. In my specific assembly, it would be somehow easier to route the coaxial cables if they were protruding from the bottom of the cavity.

Any thoughts?

That will work. I did that on several cavity filters. Depending on your soldering procedure, though, the coax may be exposed to more heavy-duty heating in that configuration. Another possibility would be to solder square, panel-mount SMA connectors on the bottom, secured with a single screw to hold them until the solder takes hold. You might have to pre-tin the connector.

You mentioned you might have a bad cable. It occurred to me that if the shield is completely cracked so there is no ground connection, the RF return for that cable will be the shield of the other cable, which might account for your mere 45 dB attenuation. I also have a cracked cable, resulting from relocating the filter and adjusting the cable angle one too many times. I soldered the shield all-around and it works fine.

Sam W.

>
> You mentioned you might have a bad cable. It occurred to me that if the shield is completely cracked so there is no ground connection, the RF return for that cable will be the shield of the other cable, which might account for your mere 45 dB attenuation. I also have a cracked cable, resulting from relocating the filter and adjusting the cable angle one too many times. I soldered the shield all-around and it works fine.

No problem. Thanks for the information.
I was under the impression that it was feasible but an expert opinion is always welcome.
Great idea of putting the sma connector directly on the bottom of the cavity. Back to the drawing board.
Many thanks

7897. Re: Parts List for Recent Group SLIMs

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-23 19:32:51 UTC
From: lh1907
Topic: 7872 Message: 7897

I'm on the home stretch. Order includes only X7R type ceramic capacitors for 0.001 uF (1 nF) and higher values and NPO or COG temp coefficient type ceramic capacitors for values below 1 nF (1000 pF).

Good idea, I'll populate one stepped attenuator with 10 or 20 dB attenuators in following order 20-10-20-10-20, This will maximize separation between adjacent 20 dB attenuators and may provide enough signal isolation without fencing between each pi-section.

The pi-network, series L, LPF values from Elsie are 42.9 nH and 11.13 pF. Nearest values at Mouser are 43 nH and 11 pF (both +- 5% tolerance). Specs are 180 MHz cutoff frequency and -30 dB at 1 GHz. Five percent limit values changes filter skirt to -28 dB at 1 GHz. I'll lower cutoff freq to generate a lower attenuation (-33 dB bogie) at 1 GHz. This should take care of L/C part value departure from calculated value. 11 pF part is available but 43 nH part is backordered with a 8 week delivery and delay warnings from supplier. DigiKey has no in stock 43 nH inductors in 805 case size. After one more iteration, if I still hit the backorder case for L part, I'll include it in order. Can use a jumper or larger L for now since Active Reflection Bridge will not be used above 30 MHz.

Since the cut off frequency for the LFCN-575D filters is well below 1 GHz, how can the MSA/TG Front End Amplifiers be used and still provide the same calibrated MSA dynamic range at 1 GHz as below LFCN-575D filter 180 MHz cut off frequency?

Larry, W2HHV

>
> X7R or X5R ceramics are great. Y5V are terrible; I don't know why they are more expensive. I didn't recall specifying tantalums in all those places. Ceramics are usually lower ESR, but are microphonic, and can generate voltages in the mV range if you tap the module. Normally that is an issue only with large value caps in a circuit with very high gain, but I have sometimes specified tantalums just to be safe. As a practical matter, though, for all these modules ceramics are fine. I suspect you will not be tapping the Cal Source while calibrating. If you were planning to use the Active Bridge or Buffer Amps at frequencies below 100 kHz, though, tantalum caps might have some benefit (due to the low frequency and possibly low signal levels involved).
>
> Yes, using two switched attenuators would eliminate any issue over changing the signal path length when swapping attenuators. (There are still small changes when flipping switches, but very minor.) If you build a second one you could just populate it with 10 or 20 dB attenuators, unless you need finer resolution for other purposes.
>
> A side note on using the switched attenuator. Phase accuracy makes it imperative that the attenuator have 50 ohm input and output impedance (high return loss) to avoid reflections that change when the settings change. It does have high return loss in the low MHz range, but terrible return loss in the 1 GHz range. LO1 signals leaking through Mixer 1 and coming out of the MSA input, reflecting off the attenuator, and then re-entering Mixer 1, can

significantly affect phase measurements (and can affect dBm measurement by a few tenths of a dB). You therefore should include a low-pass filter on the MSA input when doing phase calibration. Such a filter is doubly effective, in that if it attenuates 1 GHz by 30 dB it will attenuate LO1 on the way out and attenuate any reflections on their way back in, for a total attenuation of 60 dB (or even more, since the reflections will probably not be 100%).
>
> You can test this high-frequency reflection problem by measuring a signal with and without the lowpass filter. You would think the filter would simply reduce the dBm level due to insertion loss. In my case it actually increases the measured level by 0.2 dB by reflecting LO1 back inside. Note that reflecting LO1 is not a problem as long as the amount of reflection is fixed, and does not vary with different signal sources. The lowpass filter accomplishes that fixed reflection.

> > >
> > > The main objective of the LFCN filters is to zap signals over 1 GHz. The 575 has a cutoff far above the Active Bridge range so you could use a lower cutoff LFCN, but be sure it maintains decent attenuation in the 1-3 GHz range.
> > >
> > > 1/10 watt 0805 resistors are fine. I believe that anywhere power is at all an issue, larger sizes are specified, so we never come close to a resistor's max power.
> > >
> > > The Active Bridge uses a 78L05 or 78L06, not an LDO. The 5V version is best unless you have a use in mind that requires lowest distortion with high level drive. I used the 6V version when I tested the harmonic level for possible use with the N2PK VNA. (The harmonics were fine.)
> > >
> > > The Cal Source was originally intended to use a 2 MHz oscillator for 1 MHz output. Then I realized that the MSA zero-response (the hump around zero with no input) in VNA modes does not disappear sufficiently by 1 MHz, so it interferes with low level calibration. Even at 2 MHz, it will interfere with low level phase calibration. But if you use Scotty's optional buffer amp on the LO3 line to Mixer 3, you will zap the zero response enough that 2 MHz should work well for calibration, and even 1 MHz will be fine down to at least -80 dBm. 2 MHz should create no issues with the Switched Attenuator, except this minor issue: when you attach another attenuator to get more than the Switched Attenuator's max (57.5 dB), you will change the length of the signal path, which can affect phase calibration. If you add 2" of extra length, the effect is 0.15 degree or so. So you may want to start with a 0 dB attenuator in place (such as a barrel connector attached to a

bullet) and then replace that when you add a real attenuator. If your extra attenuator is very short, all this may not matter.

Not a dumb question, at all.
 It is fine to do as you suggest. The high current is at the point where the hairpin is soldered, either to the wall or to the base.

One (dumb?) question about the input/output coupling loops.

Instead of being grounded on the base plate would it be al right to

ground them on the tube wall (about .7" high) and then make the exit

of the coax through a couple of holes in the base plate?

I see you mention high currents in that area and this may be a problem.

In my specific assembly, it would be somehow easier to route the coaxial

cables if they were protruding from the bottom of the cavity.

Any thoughts?

While we're all on the topic of cavity filters,

I think I need to make a new one, as my first one was ... less than functional, and I was reading Sam's page about cavity filters. I was wondering if it would work to file channels on the bottoms of the pipes between chambers, just big enough for the whiskers. The reason behind the idea is that I had a really hard time drilling those holes in exactly the right places. That way, I'd only have to drill the holes for the center resonator.

Is that dumb idea??

Yes, that does work, if by whiskers you mean the coupling loops (hairpins). In theory, you are making the loop a tiny bit shorter by doing that, so the upper hole should be moved up a little, but that all may be within the margin of error.
Sam W.

Hi,

I had the same problem (my tools are limited) and I solved this by making slots instead of one holes in the bottom plate. This way I could move the hairpins closer or further from the wall (tuning it). I closed the slots with solder. The result is a bw of just under 2mhz.

The L/C values selected for the LFCN-575D filters on the MSA/TG Front End Amplifiers are 47 nH and 12 pF. The resulting Elsie frequency response is -34 dB at 1 GHz with a 160 MHz, -3 dB break frequency. The L specs on Mouser part are great: Q=40 @200 MHz, Fr=1.4 GHz, Rdc=.31 ohm, on an unshielded ceramic core. This part has an EOL notice but qty 2000 are available.

I'll place orders after breakfast.

Such a filter is doubly effective, in that if it attenuates 1 GHz by 30 dB it will attenuate LO1 on the way out and attenuate any reflections on their way back in, for a total attenuation of 60 dB (or even more, since the reflections will probably not be 100%).
> >
> > You can test this high-frequency reflection problem by measuring a signal with and without the lowpass filter. You would think the filter would simply reduce the dBm level due to insertion loss. In my case it actually increases the measured level by 0.2 dB by reflecting LO1 back inside. Note that reflecting LO1 is not a problem as long as the amount of reflection is fixed, and does not vary with different signal sources. The lowpass filter accomplishes that fixed reflection.

> > > >
> > > > The Cal Source was originally intended to use a 2 MHz oscillator for 1 MHz output. Then I realized that the MSA zero-response (the hump around zero with no input) in VNA modes does not disappear sufficiently by 1 MHz, so it interferes with low level calibration. Even at 2 MHz, it will interfere with low level phase calibration. But if you use Scotty's optional buffer amp on the LO3 line to Mixer 3, you will zap the zero response enough that 2 MHz should work well for calibration, and even 1 MHz will be fine down to at least -80 dBm. 2 MHz should create no issues with the Switched Attenuator, except this minor issue: when you attach another attenuator to get more than the Switched Attenuator's max (57.5 dB), you will change the length of the signal path, which can affect phase calibration. If you add 2" of extra length, the effect is 0.15 degree or so. Low frequency for constant differential phase through stepped attenuators and minimizing waveform edge ringing induced amplitude error but not too low for whatever reason??

7903. Re: Parts List for Recent Group SLIMs

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-24 12:53:18 UTC
From: Sam
Topic: 7872 Message: 7903

The LFCN-575D filters were intended to use that actual part from MiniCircuits. An LC filter can also work if you can get the L to span from input to output over the intervening ground connection. If you've determined that you only need 47 nH, you might get good results with a few turns of wire around a screw (then removing the screw, of course).
Sam W.

> The L/C values selected for the LFCN-575D filters on the MSA/TG Front End Amplifiers are 47 nH and 12 pF. The resulting Elsie frequency response is -34 dB at 1 GHz with a 160 MHz, -3 dB break frequency. The L specs on Mouser part are great: Q=40 @200 MHz, Fr=1.4 GHz, Rdc=.31 ohm, on an unshielded ceramic core. This part has an EOL notice but qty 2000 are available.

> >
> > Good idea, I'll populate one stepped attenuator with 10 or 20 dB attenuators in following order 20-10-20-10-20, This will maximize separation between adjacent 20 dB attenuators and may provide enough signal isolation without fencing between each pi-section.
> >
> > The pi-network, series L, LPF values from Elsie are 42.9 nH and 11.13 pF. Nearest values at Mouser are 43 nH and 11 pF (both +- 5% tolerance). Specs are 180 MHz cutoff frequency and -30 dB at 1 GHz. Five percent limit values changes filter skirt to -28 dB at 1 GHz. I'll lower cutoff freq to generate a lower attenuation (-33 dB bogie) at 1 GHz. This should take care of L/C part value departure from calculated value. 11 pF part is available but 43 nH part is backordered with a 8 week delivery and delay warnings from supplier. DigiKey has no in stock 43 nH inductors in 805 case size. After one more iteration, if I still hit the backorder case for L part, I'll include it in order. Can use a jumper or larger L for now since Active Reflection Bridge will not be used above 30 MHz.
> >

Ceramics are usually lower ESR, but are microphonic, and can generate voltages in the mV range if you tap the module. Normally that is an issue only with large value caps in a circuit with very high gain, but I have sometimes specified tantalums just to be safe. As a practical matter, though, for all these modules ceramics are fine. I suspect you will not be tapping the Cal Source while calibrating. If you were planning to use the Active Bridge or Buffer Amps at frequencies below 100 kHz, though, tantalum caps might have some benefit (due to the low frequency and possibly low signal levels involved).
> > >
> > > Yes, using two switched attenuators would eliminate any issue over changing the signal path length when swapping attenuators. (There are still small changes when flipping switches, but very minor.) If you build a second one you could just populate it with 10 or 20 dB attenuators, unless you need finer resolution for other purposes.
> > >
> > > A side note on using the switched attenuator. Phase accuracy makes it imperative that the attenuator have 50 ohm input and output impedance (high return loss) to avoid reflections that change when the settings change. It does have high return loss in the low MHz range, but terrible return loss in the 1 GHz range. LO1 signals leaking through Mixer 1 and coming out of the MSA input, reflecting off the attenuator, and then re-entering Mixer 1, can significantly affect phase measurements (and can affect dBm measurement by a few tenths of a dB). You therefore should include a low-pass filter on the MSA input when doing phase calibration. Such a filter is doubly effective, in that if it attenuates 1 GHz by 30 dB it will attenuate LO1 on the way out and attenuate any reflections on their way back in, for a total attenuation of 60 dB (or even more, since the reflections will probably not be 100%).

Sam,

About the switched attenuator shown on your website . . . does it need fencing between attenuator sections?

Thanks.

Steve K8JQ

7905. Re: Parts List for Recent Group SLIMs

Yahoo group: spectrumanalyzer (2011)
Date: 2011-03-25 13:36:14 UTC
From: Sam
Topic: 7872 Message: 7905

No fencing required. It was tested well beyond its intended frequency of use and worked well without fencing. Its attenuation and return loss remain extremely good beyond 10 MHz. They slowly deteriorate, but it still makes a functional attenuator to 500 MHz, though it is not a high precision tool beyond maybe a few tens of MHz. Phase changes between settings can be assumed negligible only for a few MHz.

I wrapped a brass sheet from one end to the other over the bottom (resistor side) just for mechanical protection. Two sides of that bottom cover are left open.

Sam W.

> > The L/C values selected for the LFCN-575D filters on the MSA/TG Front End Amplifiers are 47 nH and 12 pF. The resulting Elsie frequency response is -34 dB at 1 GHz with a 160 MHz, -3 dB break frequency. The L specs on Mouser part are great: Q=40 @200 MHz, Fr=1.4 GHz, Rdc=.31 ohm, on an unshielded ceramic core. This part has an EOL notice but qty 2000 are available.

> >>
> >> Good idea, I'll populate one stepped attenuator with 10 or 20 dB attenuators in following order 20-10-20-10-20, This will maximize separation between adjacent 20 dB attenuators and may provide enough signal isolation without fencing between each pi-section.
> >>
> >> The pi-network, series L, LPF values from Elsie are 42.9 nH and 11.13 pF. Nearest values at Mouser are 43 nH and 11 pF (both +- 5% tolerance). Specs are 180 MHz cutoff frequency and -30 dB at 1 GHz. Five percent limit values changes filter skirt to -28 dB at

1 GHz. I'll lower cutoff freq to generate a lower attenuation (-33 dB bogie) at 1 GHz. This should take care of L/C part value departure from calculated value. 11 pF part is available but 43 nH part is backordered with a 8 week delivery and delay warnings from supplier. DigiKey has no in stock 43 nH inductors in 805 case size. After one more iteration, if I still hit the backorder case for L part, I'll include it in order. Can use a jumper or larger L for now since Active Reflection Bridge will not be used above 30 MHz.
> >>
> >> Since the cut off frequency for the LFCN-575D filters is well below 1 GHz, how can the MSA/TG Front End Amplifiers be used and still provide the same calibrated MSA dynamic range at 1 GHz as below LFCN-575D filter 180 MHz cut off frequency?

> >>> X7R or X5R ceramics are great. Y5V are terrible; I don't know why they are more expensive. I didn't recall specifying tantalums in all those places. Ceramics are usually lower ESR, but are microphonic, and can generate voltages in the mV range if you tap the module. Normally that is an issue only with large value caps in a circuit with very high gain, but I have sometimes specified tantalums just to be safe. As a practical matter, though, for all these modules ceramics are fine. I suspect you will not be tapping the Cal Source while calibrating. If you were planning to use the Active Bridge or Buffer Amps at frequencies below 100 kHz, though, tantalum caps might have some benefit (due to the low frequency and possibly low signal levels involved).
> >>>
> >>> Yes, using two switched attenuators would eliminate any issue over changing the signal path length when swapping attenuators. (There are still small changes when flipping switches, but very minor.) If you build a second one you could just populate it with 10 or 20 dB attenuators, unless you need finer resolution for other purposes.
> >>>
> >>> A side note on using the switched attenuator. Phase accuracy makes it imperative that the attenuator have 50 ohm input and output impedance (high return loss) to avoid reflections that change when the settings change. It does have high return loss in the low MHz range, but terrible return loss in the 1 GHz range. LO1 signals leaking through Mixer 1 and coming out of the MSA input, reflecting off the attenuator, and then re-entering Mixer 1, can significantly affect phase measurements (and can affect dBm measurement by a few tenths of a dB). You therefore should include a low-pass filter on the MSA input when doing phase calibration. Such a filter is doubly effective, in that if it attenuates 1 GHz by 30 dB it will attenuate LO1 on the way out and attenuate any reflections on their way back in, for a total attenuation of 60 dB (or even more, since the reflections will probably not be 100%).
> >>>
> >>> You can test this high-frequency reflection problem by measuring a signal with and without the lowpass filter. You would think the filter would simply reduce the dBm level due to insertion loss. In my case it actually increases the measured level by 0.2 dB by reflecting LO1 back inside. Note that reflecting LO1 is not a problem as long as the amount of reflection is fixed, and does not vary with different signal sources. The lowpass filter accomplishes that fixed reflection.

7906. Amplifilter PCB file

Yahoo group: spectrumanalyzer (2011)
Date: 2011-04-01 07:41:15 UTC
From: davidhooau
Topic: 7906 Message: 7906

Hi Folks,

The amplifilter included in the recent filter panel is labelled 1/27/11. The ExpressPCB design file in the associated zip file is labelled 1/26/11, and has quite a few differences to the actual PCB.

Can someone point me in the direction of the correct ExpressPCB file please?

Cheers,

davidh

From: Sam
Topic: 7906 Message: 7907

In the Files section under Amplifilter.zip. The schematic was there previously, but I just replaced it with a zip file with both schematic and PCB. The PCB is probably the same as what you have. The schematic has been updated, primarily to add and reorganize the notes. Also, a new page was added with the schematic to match the layout of the consolidated RBW filter board (switch + 4 filters) that nobody has actually made yet.
Sam W.

Greg

In the files section, if you look at the document Coax filter kit assembly notes-4.doc, it contains a picture of what the response of the cavity filter should look like.

Optionally there are several pictures in Len Spyker's photo album. He has a lot of pictures but the ones showing the frequency response all start on page #2.

This may not be exactly what you are looking for but it will show you what your own filter should look like when properly tuned.

Here's one:
<http://f1.grp.yahoofs.com/v1/cOiVTQUZPTq0brRHpOBsmIpUh8NevU2RBai9kv3t9_aHfSTTH_R_LKqGdByiRs9QKId64Ouj-V5PNQ3EQBNu9w/Sam%27s%20Filter%20Plots/SSABcavityskirttest.bmp>

It's in a folder with some scans of early experimental cavities that I did. I think this one was actually Scotty's filter.

Sam W.

Hi Greg,
In the next software revision (ver16) will be a Special Test for the Cavity Filter. In the meantime, This web page shows a few plots of the Cavity Filter that is in the Verification MSA.

7915. New beta software

Yahoo group: spectrumanalyzer (2011)
Date: 2011-04-03 19:10:31 UTC
From: Sam
Topic: 7915 Message: 7915

I have uploaded the file MSA_version116_4i_Beta.zip to the Files section. It contains the latest beta software. There are various new features since the last version. Most notably, it now supports the various automated switches with USB as well as the parallel interface. I need to get feedback from anyone who has the hardware set up with USB interface and automated switches (video filter, transmit/receive, forward/reverse or 1G/2G)

Some refinements have been made to RLC Analysis and to the method for describing OSL standards. You should delete your old MSA_Info/OperatingCal/CalSets folder before using this version.

I have also totally rewritten the RLC Analysis documentation on my web site.

A nifty new feature is "MouseOver". If you click on the graph area and hold the button (left) down, info is displayed about the graphs at the frequency where you click, and the info changes as you slide the mouse around, as long as you hold down the left button. You can place a marker while using MouseOver by pressing a key on the keyboard--the numbers 1-6 or the L or R keys (without the shift key). If the Smith chart is open, it will also display info about the graph at that frequency. Among other things, this is a handy way to check things like impedance or equivalent RC or RL circuits without having to actually change the data being graphed, because the Smith chart displays a whole list of data for the selected frequency.

You can also do MouseOver directly on the Smith chart, but the results may not be quite what you expect. Info will be displayed about the point on the chart where the mouse is located, without any regard to the actual graph data. This is more for exploring the Smith chart than it is for analyzing a specific graph.

Scotty recently mentioned the cavity filter test in the Special Tests window, which has been in the last few beta versions. This lets see the cavity filer response profile so you can tune the cavity filter without having to do any rearrangement of cables.

I am still working on a glitch in Auto Wait. With my setup, it works well with the Narrow and XNarrow filters, but goes too fast with the Mid filter.

My plan is to wait for feedback on this beta and then to finalize this version, without adding any more significant features.

Sam W.

Good to know the problem is solved. I can see how that increased insertion loss, but it is a bit of a surprise that it increased the leakage of out-of-band signals. But it is what it is.

Sam
There are two kinds of fixed attenuator on the 'MSA collection' PCB, the schematic shows many configurations, which configurations do you recommend for those two attenuator small PCBs? (actually 3, 2 are identical).
Thanks
Lin

The longer board is essentially two attenuators in series and is best for large attenuation values--20 dB and above. Below that the shorter board works well and is more convenient.

From: lh1907
Topic: 7921 Message: 7921

I just completed build of Active Reflection Bridge. See the build photos in Larry_W2HHV album. The ActBridge_CapsInstalled pic shows the [4.7, 1, and 0.1] uF outlined in different colors. I installed all these caps first which made it easier to find install location for remaining components. Only change to this "first step" I would recommend is to not install C12 until after installing D1. Size wise, D1 is like a pea next to a boulder. Tweezer prong would not fit between two parts when D1 was installed second. C12 is taller and should be easier to install after D1. Using x-acto blade point and a lot of tedious poking, located the first D1 lead for solder tacking to PCB pad. The ActBridgePackaged pic is the first packaging step. The "support wall" for coax interfaces will be replaced with "SMA only" connector interfaces after the MSA/TG Front End Amplifiers and 10 dB attenuators are built and added. Without these accurate 50 ohm Reflect Input/DUT Response interfaces, the Act Bridge return loss was 36 dB at HF with a 51 ohm resistor connected to DUT test leads. Only document typo is 4.7 uF ac coupling capacitor Ref Des at DUT Response Output should be C11 (as shown on PCB silk screen). The following pretest steps are an approach to verifying build before installing ICs (U1, U2, and U3). 1.Measure all resistor values on PCB except R2 and R3. 2. Install U3 (78L05AC), apply +12 vdc In, and verify +5 vdc at pins 7 and 8 of U1 and U2. Confirm 2.5 vdc at U1-3 to show R2 and R3 values are the same. 3. Install U1, apply +12 vdc In, and 20 mv pk-pk Reflect Input signal and verify correct output at U1-6. 4. Install U2, apply +12 vdc In, and 20 mv pk-pk Reflect Input signal and verify correct output at DUT Response Output connector. The 47 nH inductor ordered for the 180 MHz filter at LFCN-575D, F1 position was too small. I used the air solenoid inductance calculator at (http://w7zoi.net/coils_zoi.zip) to wind an inductor on a 6-32 screw, back out coil from screw, and add a epoxy drop to coil. Tin wire leads before winding coil. Larry, W2HHV

Good work. You appear to be very organized. I see your point on D1. It is a tiny little demon. You input return loss of 36 dB sounds about right for 100 MHz. It should be above 50 dB at 1 MHz (depending on the accuracy of R1), but neither the input nor output return loss are very important for use as a bridge--only the DUT port return loss is important. If you want to use the bridge as a buffer amp, then those other return losses might become important. Generally, any port that leads to the MSA does not matter but the port that leads to the DUT does matter. Even a 6 dB attenuator at the DUT connection port would raise the return loss from very good to excellent. Here are two more tests to add: 1. Directivity test. Attach an accurate 50 ohm load to the DUT port. For this purpose, you could use a 0.1 % 49.9 ohm resistor to ground, soldered directly to the DUT port. Run a signal to the bridge input and record the bridge output. The output should be at least 50 dB below the input. (Directivity is the input level (dB) minus the output level (dB), or the dB value of the ratio of input voltage to output voltage.) 2. Open/Short test. Run a signal to the bridge input and record the output, with nothing attached to the DUT port. This is the Open response. Then repeat after shorting the DUT port to ground. This is the Short response. The magnitude of the Open and Short responses should be nearly identical--virtually indistinguishable at 100 kHz to a deviation of no more than 0.2 dB at 100 MHz. If you want to experiment, you can adjust Ct (1 pf) in 0.5 pf increments while performing the directivity test, to maximize the directivity at 100 MHz. From: davidhooau
Topic: 7837 Message: 7924

Hi Sam and other VGA users,

I've retested with RBW filters in place, and I'm happy the expanded log system is working correctly (and that I understand it). With the 600Hz filter, I'm getting close to 118dB range before the LD starts to plateau.

Before I nail it all shut, should I replace the VGA output transformer with a 3:1 Z ratio unit to improve the output matching?

Thanks,

davidh

> >
> > If you try adjusting VMag, you'll find that your efforts are largely defeated by the

feedback loop. For example, lowering VMag lowers the VGA gain, reducing the log amp input and therefore the feedback voltage. The lower feedback voltage increases the VGA gain, partially cancelling the effect of the original lowering of VMag. You get a similar effect if you adjust the feedback ratio.
> >
> > I suggest that you put the fencing and lid on the log detector, which is where shielding is the most important, and then check the low end response.
> >
> > I've been assuming you have the noise filter in place. Is it the 500 kHz filter? Perhaps the only difference between your response and that in my paper is the noise filter width. I used 150 kHz. In my MSA I am using 500 kHz. I did not directly test the response of the Expanded Log Detector with that wider filter, but it did not seem to affect the lowest detectable signal level at the MSA input. Possibly the Expanded Log Detector's low end response would be extended with a narrower filter, but that extra range is not reachable with my narrowest RBW filter, which is now 2 kHz. Maybe a narrower noise filter would be useful when I install my 600 kHz amplifilter. If so, I'll have to reconsider using the switchable noise filter, which would allow a wide noise filter for all RBW's except the narrowest one, where a much narrower one would kick in.
> >
> > As a rough calculation, if you input to the MSA a signal of -115 dBm and have losses of 20 dB by the time you reach the IF2 amp, the signal is -135 dBm at that point, -107 dBm at the output of the 28 dB amp, and perhaps -110 dBm at the output of the RBW filter. At that point the signal will be accompanied by noise from the amp (say, -174 dBm/Hz plus 4 created by the amp plus 28 due to amplification) equal to -142 dBm/Hz. With a 2 kHz RBW filter with 3 dB loss, that is -142+36-3=-109 dBm of noise, accompanying the -110 dBm signal. The signal would still be discernible, but there would any point in the Expanded Log Detector maintaining a strong response below the -109 dBm noise level, which is about where yours (and maybe mine) peters out. A narrower noise filter would therefore not be of much benefit. With a 600 Hz RBW filter, the noise level would be reduced by 5 dB, so a narrower noise filter might increase the low end range by 5 dB. Maybe not worth the effort.
> >
> > (Note that a detector that dies below -110 dBm can still detect a -112 dBm signal if the signal is accompanied by enough noise to push the total signal+noise over -110 dBm. The noise actually provides some benefit! The detector needs a range that extends down to the noise level, but the actual detectable signal will extend below the detector's nominal range.)

That is 7 dBm. With a gain of 6.8 dB, the AD8330 should start saturating with an input of 0.2 dBm. There would still be increased output with increased input (the output starts to square, but the fundamental content will still increase), but the response should start to flatten at 0.2 dBm input. Your response seems very linear well beyond that.

From: Sam
Topic: 7837 Message: 7927

It would be interesting to see what effect that has, but I doubt it will affect your range significantly, and it may actually reduce the range. Efficiency of power transfer is not a big issue at the VGA output (recall that I actually put an attenuator on the noise filter), so perfect impedance matching is not necessary.
Sam W.

7928. Re: VGA Gain question

Yahoo group: spectrumanalyzer (2011)
Date: 2011-04-08 12:42:46 UTC
From: Sam
Topic: 7837 Message: 7928

I should add that range of 118 dB is pretty darn good. If you want to see how far you can push it, you could try a narrower noise filter. If you have a second (wider) RBW filter, you could temporarily use that as a noise filter as an experiment.
Sam W.

>
> It would be interesting to see what effect that has, but I doubt it will affect your range significantly, and it may actually reduce the range. Efficiency of power transfer is not a big issue at the VGA output (recall that I actually put an attenuator on the noise filter), so perfect impedance matching is not necessary.

So maybe the abrupt flattening at the low end is due to the lack of shielding, as you originally suggested.
> > > >
> > > > If you try adjusting VMag, you'll find that your efforts are largely defeated by the feedback loop. For example, lowering VMag lowers the VGA gain, reducing the log amp input and therefore the feedback voltage. The lower feedback voltage increases the VGA gain, partially cancelling the effect of the original lowering of VMag. You get a similar effect if you adjust the feedback ratio.
> > > >
> > > > I suggest that you put the fencing and lid on the log detector, which is where shielding is the most important, and then check the low end response.
> > > >
> > > > I've been assuming you have the noise filter in place. Is it the 500 kHz filter? Perhaps the only difference between your response and that in my paper is the noise filter width. I used 150 kHz. In my MSA I am using 500 kHz. I did not directly test the response of the Expanded Log Detector with that wider filter, but it did not seem to affect the lowest detectable signal level at the MSA input. Possibly the Expanded Log Detector's low end response would be extended with a narrower filter, but that extra range is not reachable with my narrowest RBW filter, which is now 2 kHz. Maybe a narrower noise filter would be useful when I install my 600 kHz amplifilter. If so, I'll have to reconsider using the switchable noise filter, which would allow a wide noise filter for all RBW's except the narrowest one, where a much narrower one would kick in.
> > > >
> > > > As a rough calculation, if you input to the MSA a signal of -115 dBm and have losses of 20 dB by the time you reach the IF2 amp, the signal is -135 dBm at that point, -107 dBm at the output of the 28 dB amp, and perhaps -110 dBm at the output of the RBW filter. At that point the signal will be accompanied by noise from the amp (say, -174 dBm/Hz plus 4 created by the amp plus 28 due to amplification) equal to -142 dBm/Hz. With a 2 kHz RBW filter with 3 dB loss, that is -142+36-3=-109 dBm of noise, accompanying the -110 dBm signal. The signal would still be discernible, but there would any point in the Expanded Log Detector maintaining a strong response below the -109 dBm noise level, which is about where yours (and maybe mine) peters out. A narrower noise filter would therefore not be of much benefit. With a 600 Hz RBW filter, the noise level would be reduced by 5 dB, so a narrower noise filter might increase the low end range by 5 dB. Maybe not worth the effort.
> > > >

> > > > (Note that a detector that dies below -110 dBm can still detect a -112 dBm signal if the signal is accompanied by enough noise to push the total signal+noise over -110 dBm. The noise actually provides some benefit! The detector needs a range that extends down to the noise level, but the actual detectable signal will extend below the detector's nominal range.)

That is 7 dBm. With a gain of 6.8 dB, the AD8330 should start saturating with an input of 0.2 dBm. There would still be increased output with increased input (the output starts to square, but the fundamental content will still increase), but the response should start to flatten at 0.2 dBm input. Your response seems very linear well beyond that.

In May 2010, Brad Thompson had some
Belden Conformable (tm) 50-Ohm Coaxial Cable p/n 1671A.

His price per foot was very reasonable. Query Brad directly for current availablilty at brad.thompson(@)valley.net

Remove parenthesis from above before using: replace (@) with @

Larry, W2HHV

Davidh,

What does LD plateaus mean?

David one more question,
What is your linearity within this range?

Hi Guys,

I purchased some the conformable coax that Brad was selling (1671A). It is good cable at a great price. The only trouble with it is there doesn't seem to be a connector that fits it.
Brad said he couldn't find a suitable connector to go with it. However, it works great for Scotty's direct connection method. It has the shield that looks like it has been dipped in solder and it is very flexible. The shield won't peal back like a banana. You have to score it and break it off. It has a teflon dialectic so it is heat resistant. I just measured the outside diameter at .085". (I still have some).
He had a bunch of it a couple of years ago, I wouldn't be surprised if he still had some.

Hope this is of some help,

Bob K6GGO

Bob,
That's the tin-dipped shield version of RG-405 "hardline" (i.e. the copper tube shield), sometimes described as 0.085" and sometimes 0.086". You can use the same connectors used for the hardline. I have assembled plenty of those. You don't want to peel back the shield, you want to insert it into the connector and then solder the connector to the outside of the shield, like soldering copper plumbing pipe to a coupler.

To remove the end of the shield, I use a wire cutter (the type that has several slots for different wire sizes), apply a little pressure and rotate around the cable. I then use the same wire cutter to cut the teflon, first with an oversize cutter slot, and then with one that fits the center wire. Then check to be sure there is not a stray strand from the shield wrapped over the end that might cause a short.
Sam W.

I've been using Brad's coax for a while also. I've had success with these connectors:

Digi-key link

Also, I've got some instructions for installing them on my blog:

http://alternet.us.com/?page_id=843 (scroll to the bottom)

Finally, I've purchased from him recently (and referred him to someone that purchased in the last year), I think he's still got plenty.

Topic: 7837 Message: 7936

Hi Jurgen,

I saw very similar results to those shown in Sam's paper. I'm going to play a few more testing games, and then I'll get some results graphed to more definitively answer your (and my own) question.

As expected, the was a big improvement using an RBW filter at the input, compared with my earlier tests without. I only have the 600Hz amplifilter working at the moment but expect to add additional filters in the next few week.

HTH.

7937. Testing Crystal filters

Yahoo group: spectrumanalyzer (2011)
Date: 2011-04-09 07:19:29 UTC
From: davidhooau
Topic: 7937 Message: 7937

Folks,

This question will demonstrate how inexperienced with RF design I am....

I have a couple of crystal filters (3.7kHz and 28kHz) for which I have no data. I'm planning to use the MSA component meter mode with a series fixture to determine the impedances to match to.

How should I terminate the unused port of the filter as I test (open, short, actual impedance as measured....)?

Thanks,

davidh

7938. Re: [spectrumanalyzer] Re: VGA Gain question

Hello David,

Thanks for your reply. I logged about 14 different test combination in
an Excel spread sheet and it looks like that one is stuck with a certain
max linear range of about 110 dB in this circuit. No matter what I tried
could not get past it.
I thought the there was a possibility to expand the top end but ran into
limitations.
I finally settled for this result. I am using a 500 kHz ceramic filter
within the chain.

Jurgen

7939. Re: Testing Crystal filters

Yahoo group: spectrumanalyzer (2011)
Date: 2011-04-09 13:30:32 UTC
From: Sam
Topic: 7937 Message: 7939

That is a tricky issue. The filter output has to be terminated with the complex conjugate of its output impedance, which you don't know because that is what you are trying to find out.

The solution is in the Two Port module of the software, if you use the beta software:

1. In reflection mode, calibrate and perform a reflection mode scan that covers about 5 times the filter's bandwidth, with 200-400 steps. If you are using a series fixture with good on-board attenuation, you can use Reference calibration--no need for full OSL.
2. Change to transmission mode, calibrate and do one scan. (The reflection data is no longer graphed but still exists.
3. Open the Two Port module under the Two Port menu.
4. It asks you what to do with the data. Tell it to transfer the reflection data to both S11 and S22, and the transmission data to S21 and S12. A graph of the data will be shown, showing the performance of the filter with 50 ohm source and load. If you select the S21 graph, it will look bad.
5. Click Change Terminations, which opens a window that lets you see the performance with other terminations.
6. Click Auto Match, specifying Simultaneous match. This will calculate the source and load impedances that create the desired conjugate match on both input and output, and will take into account the circular complication that the value of the load impedance will affect the desired source impedance.
7. It will also show the components that create the desired impedance, and you have the choice of several configurations. If you change the configuration, re-click Auto Match.
8. You can click a button for a parameter to graph it, showing the response with the calculated termination. You want to confirm that S21 looks good.

Matching components are calculated as though you are using a transformer to do the resistive match, with an inductor or capacitor adjacent to the filter to provide the desired reactance. The configuration you probably want is a shunt capacitor on input and output. You then calculate (with RFSim99) the impedance matching circuit to transform the impedance from 50 to the resistance calculated by Auto Match, in the form of a series Inductor followed by a shunt capacitor at the filter input. At the output, the capacitor will come before the inductor, so in both cases the RFSim-calculated capacitor is adjacent to the filter, as is the AutoMatch-calculated capacitor. You just combine the adjacent capacitors into one by adding them together (even if one has a negative value).

Sam W.

From: Sam
Topic: 7837 Message: 7940

Jurgen,
The main potential for greater range is the use of very narrow RBW filters and/or a narrow noise filter. I would expect that the combination of an RBW filter below 1 kHz with a noise filter of 7.5 kHz would improve the low end. That would of course require using a switchable noise filter, though as an experiment you could manually swap the noise filters. I have not tried these narrow filters.
Sam W.

Hi Guys,

That is great news. Now I can use this stuff for jumpers. I don't know where I got it in my head that there were no connectors for that cable. I think I read it somewhere.
I have to admit when I measured it at .085" I thought to myself," thats a standard size, hard to believe there's no connectors made for that". Obviosly I never checked.

At any rate, now I can make better use of the stuff, and that's a good thing.

Thanks,

Bob

There are plenty of oriental SMA knockoffs that will fit 0.085 cables. Try surfing EBAY. I do not remember where I got mine. There are some good old expensive USA connectors too. Unless I am using the wrong ones!!!

Hi Guys,

I purchased some the conformable coax that Brad was selling (1671A). It is good cable at a great price. The only trouble with it is there doesn't seem to be a connector that fits it.

Brad said he couldn't find a suitable connector to go with it. However, it works great for Scotty's direct connection method. It has the shield that looks like it has been dipped in solder and it is very flexible.

The shield won't peal back like a banana. You have to score it and break it off. It has a teflon dialectic so it is heat resistant. I just measured the outside diameter at .085". (I still have some).

He had a bunch of it a couple of years ago, I wouldn't be surprised if he still had some.

Hope this is of some help,

Bob K6GGO

In May 2010, Brad Thompson had some

Belden Conformable (tm) 50-Ohm Coaxial Cable p/n 1671A.

His price per foot was very reasonable. Query Brad directly for current availablilty at

brad.thompson(@)valley.net

Remove parenthesis from above before using: replace (@) with @

Other Bob,

Sam is correct. Another way to strip it is to score the shield with a SHARP razor knife while "rolling" the cable on your bench. You will "feel" when you have cut through the shield. You can then just pull it off. I find this bit easier than the pipe cutter approach. But, I have arthritic hands.

Bob,

That's the tin-dipped shield version of RG-405 "hardline" (i.e. the copper tube shield), sometimes described as 0.085" and sometimes 0.086". You can use the same connectors used for the hardline. I have assembled plenty of those. You don't want to peel back the shield, you want to insert it into the connector and then solder the connector to the outside of the shield, like soldering copper plumbing pipe to a coupler.

To remove the end of the shield, I use a wire cutter (the type that has several slots for different wire sizes), apply a little pressure and rotate around the cable. I then use the same wire cutter to cut the teflon, first with an oversize cutter slot, and then with one that fits the center wire. Then check to be sure there is not a stray strand from the shield wrapped over the end that might cause a short.

7944. Re: VGA Gain question

Yahoo group: spectrumanalyzer (2011)

From: davidhooau
Topic: 7837 Message: 7944

Hi Jurgen,

In the "davidh build" area of the photo section is a graph of the VGA system prior to using the 600Hz RBW filter. For this, the LD was shielded, the VGA and NF open.

For the LD alone, there's almost 100dB of range (-90..+10dBm). I have not plotted the errors for this test.

For the VGA system with no RBW filter, there's about an additional 10dB that is usable with good calibration (-107..+3dBm). For this range, the absolute error ranges from about +2dBm at the bottom and the top, and by adjusting the gain equation I've used, I can move the error graph downwards to better "pick" the upper and lower limits.

With the 600Hz filter and the NF and VGA shielded (no graph), the flattening of the bottom end is extended to around -115dBm, where the error term is about 2dBm. This is my (quite arbitrary) determinant of usable range.

To perform these tests, I used a sig gen and attenuator directly into the VGA or amplifilter inputs. Neither of these devices are in cal or have been accurately measured, so perhaps my system is a lot worse (or a lot better) than these tests indicate.

One thing that does come out of these tests is that I'm going to need to replace my IFA with a LN amp of some sort.

I'm in the process of shielding all of the SLIMs currently, so I'll try to get back to VGA games in the next few days. Unfortunately wo*k (sorry Scotty, I've tried to hide the word from you) gets in the way.

davidh

7945. Re: VGA Gain question

Yahoo group: spectrumanalyzer (2011)
Date: 2011-04-09 21:45:43 UTC
From: Sam
Topic: 7837 Message: 7945

This brings up a good point about how you determine the low end. As you lower the signal level, the response, in ADC value per dB, eventually starts to fall. When it gets too small, you are out of range, but there is no precise level of "too small". A good guideline is that when the ADC changes less than 10 for a change of 1 dB, it will be difficult to make use of that response. Another way to do it is to use the initial calibration procedure with the largest video filter and click Measure repeatedly at input of, say, -111 dBm, and then do the same with -110 dBm. If the ADC readings for -110 dBm are consistently higher than those for -111 dBm, then you can consider -110 dBm to be within the usable range.

A graphical way to do it is to scan a narrow range around, say, 5 MHz, with the largest video filter, inputting a low level signal. At very low levels, the signal will show a small bump, whose exact shape will change from sweep to sweep due to noise. But if you can consistently see that the bump is there, you can consider that signal level to be within the usable range. The smallest such signal is the Minimum Visible Signal.

The accuracy of measurements of the very lowest level signals will not be great, due to noise. Measurement of the Minimum Visible Signal as determined above may be off by several dB. But in many cases your only concern at such levels is whether the signal is even there, and determining its precise level is not critical.

At one point, I determined that my Minimum Visible signal with a 2 KHz RBW filter was -113 dBm (at the MSA input), even though I could distinguish (barely) -124 dBm from -125 dBm if I took enough readings and averaged the ADC values.

Interestingly, the useful range in VNA modes extends a bit below the Minimum Visible Signal, because you unconsciously perform your own visual averaging. If you look at a filter response dropping slowly below the Minimum Visible Signal, noise may cause it to make erratic up and down movements, but the downward trend may still be clear. This may give you more than 5 dB of additional range.

Sam W.

>
> For the VGA system with no RBW filter, there's about an additional 10dB that is usable with good calibration (-107..+3dBm). For this range, the absolute error ranges from about +2dBm at the bottom and the top, and by adjusting the gain equation I've used, I can move the error graph downwards to better "pick" the upper and lower limits.

>
> With the 600Hz filter and the NF and VGA shielded (no graph), the flattening of the bottom end is extended to around -115dBm, where the error term is about 2dBm. This is my (quite arbitrary) determinant of usable range.

From: Jurgen
Topic: 7837 Message: 7946

Sam,

Are you talking about the filter bandwidth within the VGA chain?
Remember my tests include the VGA chain only.
I am just getting into it again. Work gets into the way.
I finally have my new scope going, probing etc.
I also have the PCB's I promised, the size turned out ~ 1mm larger than
the others. Don't why looks like I did not pay attention.
I will ship them soon.

Jurgen

You can't pin down the full range until you have the full chain of IF2 Amp--RBW filter--VGA--Noise Filter--Log Detector. The narrowness of the RBW filter and noise filter affects the low end range up to a point. Narrowing a filter improves the range only if that filter is the bottleneck in the noise reduction plan. To see how far you can extend the range, it is probably best to start with very narrow filters. If it turns out, for example, that very narrow filters have a range of only 5 dB more than you get with wider filters, you might decide the using the switchable noise filter is not worth the trouble.

When I did my testing, I did not have an extremely narrow RBW filter, nor did I try a noise filter narrower than 60 kHz. Now that I have the 600 Hz amplifilter, I plan to use it to replace my 2 kHz RBW filter, which I can then try as the noise filter. (The noise filter does not have anywhere near as much attenuation as the RBW filters, but an extra RBW filter is convenient to use for an experiment.)
Sam W.

7948. Re: [spectrumanalyzer] Re: VGA Gain question

Yahoo group: spectrumanalyzer (2011)
Date: 2011-04-10 16:04:55 UTC
From: Jurgen
Topic: 7837 Message: 7948

You might remember initially I used the 60kHz ceramic filter as a noise filter then after some deliberation I changed it back to 600 kHz. According to my record this extended the low range by an additional 5dB. I am looking forward to the results of putting a 2kHz filter into its place.
Jurgen

7949. Call for Help

Yahoo group: spectrumanalyzer (2011)

Topic: 7949 Message: 7949

Hi All,
I have determined that the MUN2211 buffer transistor, used in the AtoD Converter Module, needs to be replaced with a different device. Although it works as intended, it's speed is a bottle neck for the new USB control.
The best possible replacement is an open drain FET that has a gate turn-on characteristic of standard CMOS logic.
There are literally hundreds of these devices on the market and I don't have the time or testing capability to do the proper research. So, I am asking for a little help. Those of you who have a good "junk-box", find one and test it in your AtoD module. Here are the requirements:
* Size: SOT-23, SOT-23-3, TO-236, case 318-80. This is the pad size on the pwb of the AtoD.
* N-channel
* Enhancement mode
* Gate threshold: 1.0v to 3.0v, 2.5 volt preferred.
* Open Drain
* Pin-outs: Drain, top single pin; Gate, lower left pin; Source, lower right pin
* Maximum continuous current: at least 5 ma.
* Maximum drain voltage: at least 10 volts
* Turn-on and turn-off delay: 500 nsec or faster.
* Internal diode protection
* Available at Digikey in single quantities (cheap)

Here are a couple of devices that meet the reqmts. You can use their data sheets as examples in your search.
http://www.onsemi.com/pub_link/Collateral/2N7002E-D.PDF
http://www.diodes.com/datasheets/ZVN3310F.pdf

If you think you have a good device but cannot test it yourself, post to the group and arrange to send it to someone who can test it.

Scotty

My vote would be a 2N7002.

Greg

7951. Variations to the MSA

Yahoo group: spectrumanalyzer (2011)

Attachments: 1 described; binary payloads are missing from this source WARC

Hi all,

I was having a problem with too many coax intertwining in my box so I decided to do some pruning.

First I separated the newly added PLO2 post-amplifier from the TG buffer. I created two separate PCBs , encapsulated them in a round copper bushing, and plugged them directly into the PLO2 and MXr 3 SMAs (2 pigtails pruned)

Second (this is huge!), using a layout by SamW which combines the RBW switch and four filters into a single board I was able to eliminate 8 pigtails (with connectors). Also a regained acres of real estate.

See the attached file for the bloody results.

Now I have two RBW 3.8x2.5" combo boards ($20 each) and two pairs of amplifiers ($10 per pair) that I'll be happy to part from. If interested just drop me a note. Sorry, no shipping overseas.

Jim, W1JGH

7952. Re: VGA Gain question

Yahoo group: spectrumanalyzer (2011)

From: Sam
Topic: 7837 Message: 7952

Here is the state of the experiment so far. I replaced the 2 kHz RBW filter with the 600 Hz amplifiliter. Low end remained about -114 dBm. This indicated the bottleneck is the noise filter. Started to replace the 500 kHz noise filter with the 2 kHz filter, then remembered the amplifilter is centered at 10.693 MHz and the 2 kHz filter is at 10.7 MHz, so the pass bands don't overlap. Found a ceramic filter that was about 150 kHz BW and used it as the noise filter. Low end dropped to -119 dBm. Still gets good response at +7 dBm at MSA input. That's a range of 126 dB.

Low end was measured as the level at which the slope of ADC value per dB dropped to 10.

The drop in the low end was proportional to the reduction in noise filter bandwidth (10*log(500kHz/150kHz)=5.2 dB). This suggests that there is more to be gained by an even narrower noise filter. I will see what I can rig up.

Sam W.

Topic: 7951 Message: 7953

Jim, is the entire RBW board now fully functional?

To All: To this point, the RBW filters have been "to each his own". But ceramic filters seem to take care of the two broadest filters quite well, and the amplifilter is a simple way to handle the narrowest filter. That leaves only the second-narrowest filter, probably something in the 2-7.5 kHz range. If you use Jim's board, you'll have a nice, compact collection of filters that is simple to build, with the possible exception of the 2-7.5 kHz filter, which is a custom 5-filter design that will require some tuning. However, the board is also designed so that you can use an MCF design (per Lin's posted files) instead of the crystals, which would allow a 7.5 kHz design with ECS filters. Or, you could add SMA connectors to bypass the on-board layout and attach a canned filter, such as the 7.5 kHz ITT filter that several people have built.

As Jim stated, the biggest advantage of the unified RBW board is all the connectors it eliminates (8 male and 8 female), as well as the cables. That not only eliminates a lot of hassle, but saves a lot of space.

If you already have your filters put together, you may not want to use this board (I'm sticking with what I have). But if you have not yet built the filters, this board is definitely the way to go.

At this moment the switch, amplifilter and ceramics are completed. The 5 crystal section (5 kHz) is missing the tuning inductors from Mouser. No fences yet.
I will test it before fencing though.

There is a lot of flexibility built into the 5 crystal area , maybe too much, but nothing that a jumper will not solve.
I found some tight spots but again nothing horrible.

I have been busy working with the YIG project, most of the problems related with measuring (guesstimating rather) power at 8 Ghz. Very happy with the Hittite divide by 8 prescaler, I am planning to use one for my frequency meter so I should be reading up to 12 GHz. They sell them in multiples of ten so if there is enough interest we could make a group buy.

7955. Re: VGA Gain question

Yahoo group: spectrumanalyzer (2011)
Date: 2011-04-12 15:37:34 UTC
From: Sam
Topic: 7837 Message: 7955

And now for the final conclusion. I replaced the 150 kHz noise filter with 75 kHz, for a 3 dB bandwidth reduction. There was possibly a tiny improvement, with the low end maybe dropping by 1 dB to -120 dBm. But I think this indicates that there is nothing to be gained by making the noise filter bandwidth anything lower than 75 kHz, unless the RBW filter could also be narrowed.

-120 dBm is nice round number, so I'm going with that as the low end. The highest level I tested is +7 dBm, so I have range of at least 127 dB. The response at +7 is still good, so it probably can do a bit more. At the high end there will be a lot of distortion, and I'm sure phase inaccuracy, but above 0 dBm it should still be good for power measurement of isolated signals.

The 75 kHz noise filter bandwidth will not work with wide RBW filters. Even a 60 kHz RBW might not work because the ceramic noise filter might not be precisely centered at 10.7 MHz. But the 75 kHz noise filter is probably only effective with a very narrow RBW anyway. To utilize the narrow noise filter, it is necessary to use the switchable noise filter so a wider noise filter will kick in for the wider filters. My switchable noise filter has an op amp and a switch, because I was trying to avoid loss. It turns out that loss in the noise filter is of little concern, since it just has the effect of cranking up the VGA gain. I actually have mine set with fairly low op amp gain, so there is a fair amount of loss.

I designed a newer switchable noise filter that uses a switch but omits the op amp. It could probably be further simplified because the narrow noise filter can be used with the two narrowest filters, and the wide filter with the others (my wide filter will become 1 MHz). If the filters are addressed 0-3 starting from the widest (that's how it is done on the unified RBW board), that means the switching can be done with an SPDT driven by the "2" bit of the address, and the "1" bit can be ignored.

>
> Here is the state of the experiment so far. I replaced the 2 kHz RBW filter with the 600 Hz amplifiliter. Low end remained about -114 dBm. This indicated the bottleneck is the noise filter. Started to replace the 500 kHz noise filter with the 2 kHz filter, then remembered the amplifilter is centered at 10.693 MHz and the 2 kHz filter is at 10.7 MHz, so the pass bands don't overlap. Found a ceramic filter that was about 150 kHz BW and used it as the noise filter. Low end dropped to -119 dBm. Still gets good response at +7 dBm at MSA input. That's a range of 126 dB.
>
> Low end was measured as the level at which the slope of ADC value per dB dropped to 10.
>
> The drop in the low end was proportional to the reduction in noise filter bandwidth (10*log(500kHz/150kHz)=5.2 dB). This suggests that there is more to be gained by an even narrower noise filter. I will see what I can rig up.

Topic: 7837 Message: 7956

One further comment. I used a 28 dB IF2 amp instead of Scotty's 40 dB amp. I'm wary of blasting too much power through the RBW filters with high level MSA inputs. But if you are willing to go with the higher power through the filters, you can use the 40 dB amp with the Expanded Log Detector, and perhaps pick up another 10 dB on the low end, though you will possibly lose some of that from the high end.
Sam W.

>
> And now for the final conclusion. I replaced the 150 kHz noise filter with 75 kHz, for a 3 dB bandwidth reduction. There was possibly a tiny improvement, with the low end maybe dropping by 1 dB to -120 dBm. But I think this indicates that there is nothing to be gained by making the noise filter bandwidth anything lower than 75 kHz, unless the RBW filter could also be narrowed.
>
> -120 dBm is nice round number, so I'm going with that as the low end. The highest level I tested is +7 dBm, so I have range of at least 127 dB. The response at +7 is still good, so it probably can do a bit more. At the high end there will be a lot of distortion, and I'm sure phase inaccuracy, but above 0 dBm it should still be good for power measurement of isolated signals.
>
> The 75 kHz noise filter bandwidth will not work with wide RBW filters. Even a 60 kHz RBW might not work because the ceramic noise filter might not be precisely centered at 10.7 MHz. But the 75 kHz noise filter is probably only effective with a very narrow RBW anyway. To utilize the narrow noise filter, it is necessary to use the switchable noise filter so a wider noise filter will kick in for the wider filters. My switchable noise filter has an op amp and a switch, because I was trying to avoid loss. It turns out that loss in the noise filter is of little concern, since it just has the effect of cranking up the VGA gain. I actually have mine set with fairly low op amp gain, so there is a fair amount of loss.
>
> I designed a newer switchable noise filter that uses a switch but omits the op amp. It could probably be further simplified because the narrow noise filter can be used with the two narrowest filters, and the wide filter with the others (my wide filter will become 1 MHz). If the filters are addressed 0-3 starting from the widest (that's how it is done on the unified RBW board), that means the switching can be done with an SPDT driven by the "2" bit of the address, and the "1" bit can be ignored.

> >
> > Here is the state of the experiment so far. I replaced the 2 kHz RBW filter with the 600 Hz amplifiliter. Low end remained about -114 dBm. This indicated the bottleneck is the noise filter. Started to replace the 500 kHz noise filter with the 2 kHz filter, then remembered the amplifilter is centered at 10.693 MHz and the 2 kHz filter is at 10.7 MHz,

so the pass bands don't overlap. Found a ceramic filter that was about 150 kHz BW and used it as the noise filter. Low end dropped to -119 dBm. Still gets good response at +7 dBm at MSA input. That's a range of 126 dB.
> >
> > Low end was measured as the level at which the slope of ADC value per dB dropped to 10.
> >
> > The drop in the low end was proportional to the reduction in noise filter bandwidth (10*log(500kHz/150kHz)=5.2 dB). This suggests that there is more to be gained by an even narrower noise filter. I will see what I can rig up.

7957. Re: VGA Gain question

Yahoo group: spectrumanalyzer (2011)
Date: 2011-04-14 17:03:13 UTC
From: Sam
Topic: 7837 Message: 7957

I now have the switched noise filter properly shielded and installed in the MSA. It ties into the RBW Switch control lines. Here is my low end with various filters:

RBW=600Hz NoiseFilt=75kHz LowEnd=-121 dBm
RBW=8kHz NoiseFilt=75kHz LowEnd=-112 dBm
RBW=60kHz NoiseFilt=1MHz LowEnd=-105 dBm
RBW=400kHz NoiseFilt=1MHz LowEnd=-97 dBm

In all cases the response tested well to +7 dBm, which is the highest level I can conveniently test.

Sam W.

>
> One further comment. I used a 28 dB IF2 amp instead of Scotty's 40 dB amp. I'm wary of blasting too much power through the RBW filters with high level MSA inputs. But if you are willing to go with the higher power through the filters, you can use the 40 dB amp with the Expanded Log Detector, and perhaps pick up another 10 dB on the low end, though you will possibly lose some of that from the high end.
> Sam W.
>
> --- In spectrumanalyzer@yahoogroups.com, "Sam" <swetterlin@> wrote:
> >
> > And now for the final conclusion. I replaced the 150 kHz noise filter with 75 kHz, for a 3 dB bandwidth reduction. There was possibly a tiny improvement, with the low end maybe dropping by 1 dB to -120 dBm. But I think this indicates that there is nothing to be gained by making the noise filter bandwidth anything lower than 75 kHz, unless the RBW filter could also be narrowed.
> >
> > -120 dBm is nice round number, so I'm going with that as the low end. The highest level I tested is +7 dBm, so I have range of at least 127 dB. The response at +7 is still good, so it probably can do a bit more. At the high end there will be a lot of distortion, and I'm sure phase inaccuracy, but above 0 dBm it should still be good for power measurement of isolated signals.
> >
> > The 75 kHz noise filter bandwidth will not work with wide RBW filters. Even a 60 kHz RBW might not work because the ceramic noise filter might not be precisely centered at 10.7 MHz. But the 75 kHz noise filter is probably only effective with a very narrow RBW anyway. To utilize the narrow noise filter, it is necessary to use the switchable noise filter so a wider noise filter will kick in for the wider filters. My switchable noise filter has an op amp and a switch, because I was trying to avoid loss. It turns out that loss in the noise filter is of little concern, since it just has the effect of cranking up the VGA gain. I actually have mine set with fairly low op amp gain, so there is a fair amount of loss.
> >
> > I designed a newer switchable noise filter that uses a switch but omits the op amp. It

could probably be further simplified because the narrow noise filter can be used with the two narrowest filters, and the wide filter with the others (my wide filter will become 1 MHz). If the filters are addressed 0-3 starting from the widest (that's how it is done on the unified RBW board), that means the switching can be done with an SPDT driven by the "2" bit of the address, and the "1" bit can be ignored.

> > >
> > > Here is the state of the experiment so far. I replaced the 2 kHz RBW filter with the 600 Hz amplifiliter. Low end remained about -114 dBm. This indicated the bottleneck is the noise filter. Started to replace the 500 kHz noise filter with the 2 kHz filter, then remembered the amplifilter is centered at 10.693 MHz and the 2 kHz filter is at 10.7 MHz, so the pass bands don't overlap. Found a ceramic filter that was about 150 kHz BW and used it as the noise filter. Low end dropped to -119 dBm. Still gets good response at +7 dBm at MSA input. That's a range of 126 dB.
> > >
> > > Low end was measured as the level at which the slope of ADC value per dB dropped to 10.
> > >
> > > The drop in the low end was proportional to the reduction in noise filter bandwidth (10*log(500kHz/150kHz)=5.2 dB). This suggests that there is more to be gained by an even narrower noise filter. I will see what I can rig up.

Hello Scotty,

Could you jog my memory please, what was the value of R23 on the PLO for the ADF4113.
I seem to remember 4.7k. Is that correct?

Thanks, Jurgen

7959. Re: VGA Gain question

Yahoo group: spectrumanalyzer (2011)
Date: 2011-04-15 22:29:00 UTC
From: Sam
Topic: 7837 Message: 7959

I have recalibrated my MSA due to all my recent tinkering. I posted a graph of the mag cal table for the amplifilter (600Hz) path:
<http://groups.yahoo.com/group/spectrumanalyzer/photos/album/271352628/pic/517713427/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc>

The graph shows very nice linearity for the range from -109 dBm to -1 dBm, with some curvature outside that range. Response at the low end eventually becomes very poor due to noise. Response at the high end deteriorates largely because Mixer 1 starts to saturate, but the deterioration up to 8 dBm is not all that bad, at least for the purpose of measuring the power of a signal. (I have 3 dB attenuation in the RF input of Mixer 1, so 8 dBm at the MSA input becomes 5 dBm at the mixer.)

Sam W.

> >
> > One further comment. I used a 28 dB IF2 amp instead of Scotty's 40 dB amp. I'm wary of blasting too much power through the RBW filters with high level MSA inputs. But if you are willing to go with the higher power through the filters, you can use the 40 dB amp with the Expanded Log Detector, and perhaps pick up another 10 dB on the low end, though you will possibly lose some of that from the high end.
> > Sam W.
> >
> > --- In spectrumanalyzer@yahoogroups.com, "Sam" <swetterlin@> wrote:
> > >
> > > And now for the final conclusion. I replaced the 150 kHz noise filter with 75 kHz, for a 3 dB bandwidth reduction. There was possibly a tiny improvement, with the low end maybe dropping by 1 dB to -120 dBm. But I think this indicates that there is nothing to be gained by making the noise filter bandwidth anything lower than 75 kHz, unless the RBW filter could also be narrowed.
> > >

> > > -120 dBm is nice round number, so I'm going with that as the low end. The highest level I tested is +7 dBm, so I have range of at least 127 dB. The response at +7 is still good, so it probably can do a bit more. At the high end there will be a lot of distortion, and I'm sure phase inaccuracy, but above 0 dBm it should still be good for power measurement of isolated signals.
> > >
> > > The 75 kHz noise filter bandwidth will not work with wide RBW filters. Even a 60 kHz RBW might not work because the ceramic noise filter might not be precisely centered at 10.7 MHz. But the 75 kHz noise filter is probably only effective with a very narrow RBW anyway. To utilize the narrow noise filter, it is necessary to use the switchable noise filter so a wider noise filter will kick in for the wider filters. My switchable noise filter has an op amp and a switch, because I was trying to avoid loss. It turns out that loss in the noise filter is of little concern, since it just has the effect of cranking up the VGA gain. I actually have mine set with fairly low op amp gain, so there is a fair amount of loss.
> > >
> > > I designed a newer switchable noise filter that uses a switch but omits the op amp. It could probably be further simplified because the narrow noise filter can be used with the two narrowest filters, and the wide filter with the others (my wide filter will become 1 MHz). If the filters are addressed 0-3 starting from the widest (that's how it is done on the unified RBW board), that means the switching can be done with an SPDT driven by the "2" bit of the address, and the "1" bit can be ignored.

> > > >
> > > > Here is the state of the experiment so far. I replaced the 2 kHz RBW filter with the 600 Hz amplifiliter. Low end remained about -114 dBm. This indicated the bottleneck is the noise filter. Started to replace the 500 kHz noise filter with the 2 kHz filter, then remembered the amplifilter is centered at 10.693 MHz and the 2 kHz filter is at 10.7 MHz, so the pass bands don't overlap. Found a ceramic filter that was about 150 kHz BW and used it as the noise filter. Low end dropped to -119 dBm. Still gets good response at +7 dBm at MSA input. That's a range of 126 dB.
> > > >
> > > > Low end was measured as the level at which the slope of ADC value per dB dropped to 10.
> > > >
> > > > The drop in the low end was proportional to the reduction in noise filter bandwidth (10*log(500kHz/150kHz)=5.2 dB). This suggests that there is more to be gained by an even narrower noise filter. I will see what I can rig up.

Hi Jurgen,
 Yes, 4.7 K is correct.

Hello Scotty,

Could you jog my memory please, what was the value of R23 on the PLO
for the ADF4113.

I seem to remember 4.7k. Is that correct?

Thanks, Jurgen

On 8/29/2010 12:00 AM, william sprowls wrote:

Hi Jim,

 Hopefully, Sam helped you fix your problem. I was
going to advise to be sure to add R23 for the
ADF4113. Same footprint as the LMX but it doesn't
use R23.

 I think you are the first using the 4113. I will
be interested to know the outcome of its total
phase noise. It is supposed to exhibit a little
less phase noise than the LMX. I'm guessing you
might see a 1 or 2 dB improvement.

Scotty

Has anyone been succesful with the ADF4113 or 4112 instead of the LMX?

I built my PLO3 with the ADF4113, including the extra resistor, and on start up it climbs the control voltage to the VCO from 0 to 22.2 volts and STAYS THERE. The 10.7 square signal from the DDS is identical to the one in PLO1 and all voltages and currents appear to be OK. Changing Modes does not change anything. I am truly stumped.

Having just re-calibrated, I went through my document describing the process and made changes/corrections. I updated the document InitialCal.pdf in the Files section.

For one thing, I previously described frequency calibration before path calibration, but you need to have at least a partial path calibration before the frequency calibration will be valid.

I previously described complications involving the zero-hump or zero-response, which can require doing low level phase calibrations at a higher frequency. Now I note that this is not an issue if you install the optional LO2 Isolation Amp.

It is handy to do magnitude calibration and phase calibration separately. During magnitude calibration, it is nice to be able to force the phase correction to zero, or in the case of very low signal levels, to 180. A phase correction of 180 signals the MSA that phase measurement at that level is not meaningful, so it will be graphed as zero. The new software will have a mechanism to force the phase correction to a desired value, so you don't have to manually change all the entries.

Speaking of the new software, as far as I'm concerned it is ready for release. But if anyone knows of any bugs in the beta software, please let me know. Particularly with regard to USB, which I am currently not able to test.

Sam W.

Hello Scotty,

Another question. I build all three PLO's identical ("standard PLO"). An oversight on my part.

I can not make the "standard PLO" work in the PLO2 slot. It either latches at 2.1 GHz or 800 some MHz with distorted waveform. It flip flops. Is it possible that the code would have to changed to accommodate a "standard PLO"?

I have +20V connected. I see data bits on the clock line and data line but none on LE, it is low.
Looking at the data sheet data is transferred during a positive transition on LE.
I understand from Sam that LE is activated during initialization only.

Thanks for your help, Jurgen

I hope I can answer this question correctly...

If you build PLO2 with an opamp, then it's "inverting" and you need to change that in the hardware configuration settings in the Spectrum Analyzer software. This is a flag that must be set in the PLL chip so it inverts the charge pump output.

Good point, Will. Jurgen, in the Configuration Manager you need to set the PLL2 "polarity" to match that of PLL1 and 3. Ignore the "invert" and "non-inv" labels, which we recently realized are reversed. Just make PLL2 match PLL1.
Sam W.

Thanks, William.
That certainly makes sense, the Op amp is inverting. I hope this is all
that needs to be done.
Now I have to equip myself with the compiler, source code etc. etc.

Jurgen

Thanks, sounds good. Made the change, I glad I don't have to get into
the code.
Will retest later.

Jurgen

7968. Circuit Board Source

Yahoo group: spectrumanalyzer (2011)
Date: 2011-04-21 14:13:19 UTC
From: Robert Fish
Topic: 7968 Message: 7968

Hi Guys,

I was surfing the web this morning and stumbled across the Far Circuits website while researching a different project. Far circuits has been around for a while.
I have purchased pre-made circuit boards from them in the past.

Here is the link: http://www.farcircuits.net/

On their site they offer to make boards from ExpressPCB files.

Here is the text from the pricing page:
/
FAR Circuits now will accept Express PCB files and make the required boards from your files. Just email mail@... your Express PCB files.

Pricing is as follows:
All boards are made of G-10, FR-4 material, 1 oz. copper, solder coated, and drilled.
Double sided boards DO NOT have plated through holes.
Custom boards may be made for $.50 square inch or $5.00 minimum per board for single sided, etched, drilled and solder coated. A film shot is required for the solder side and the legend at $10.00 per shot.
Custom double sided non-plated through holes, etched, drilled and solder coated boards may be made for $.75 per square inch or $8.00 minimum per board. A film shot is required for the solder side, component side, and the legend at $10.00 per shot.

Quantity pricing available. Far Circuits reserves the right to change the pricing based on the complexity of the board. FAR Circuits offers layout and prototype services. Please call or us if you have any questions./

I am not sure I understand all of that, or if it is any cheaper than express PCB themselves, but here is the info never the less. It might be a good way to have boards made.

Bob

Bob,
The lack of plated-through holes sounds like a killer to me, unless you enjoy soldering Z-wires. But maybe it would be good for special purpose boards that might be single-sided, or might have a small number of vias.
Sam W.

Hi All,
I happened to notice that the "Hit" counter on the MSA web page just went over one-half million. I wanted to stop and thank each and every one of you for showing interest in the MSA Project. It warms my heart that this and many other "Do-It-Yourself" projects have gained popularity. The nay-sayers had given "DIY" projects the death knell. Bologna, they will continue because there is great satisfaction in building something useful with your God-given talents.

If you're willing to use a program other than expressPCB, there are TONS of great places for cheap boards, here are 2 examples:

iTead studio: Double-sided (plated through holes) 6-6 (min. trace/spacing in mils) with soldermask and silkscreen
Within 5x5cm square $12 for 10 boards
Within 10x10cm square $28 for 10 boards

Hey have lots more options, but those are the most generic
http://iteadstudio.com/store/index.php?main_page=index&cPath=19_20

Also, BatchPCB: Double-sided (plated through holes) 8-8 (min. trace/spacing in mils) with soldermask and silkscreen
$0.25 per Sq. inch $10 setup per order (can be many designs)

OUTSTANDING Scotty

The contributions of you and others is wonderful to see
and the evolution of this project is fascinating.

I remember what one of my professors presented to us long
ago and in a far away galaxy; "The quality of the observation
is not in the number of individual observations but in the
number of observers." Your website invites this breadth which
should be the envy of many engineering groups.

Best Regards;

Greg

Scotty et al,

To be sure many of us who belong to this group feel the same as you. Also worth mentioning is the "sharing" of those skills, knowledge and joys. And the whole group started with Scotty. No amount of wealth could replace and/or buy this.

Thanks Scotty et al.

7975. Log Det/VGA Ckt Values for Expanded Log Amp

Yahoo group: spectrumanalyzer (2011)
Date: 2011-04-21 17:10:56 UTC
From: lh1907
Topic: 7975 Message: 7975

After reviewing the following info:

1. Expanded-Range Log Detector, updated 9/25/10 (Sam W's white paper);
2. Following schematics in ExpandedLog.sch file:
a. Log Detector, Rev 1.1, 3/15/10, and
b. VGA, Rev 1.1, 9/10/10; and
3.Log Detect PCB SEW Mod 3/15/10.

I could not reconcile the following aspects of Fdbk interface from Log Det to VGA.

A. The R/C values at Log Det MagVolts source is 220 ohm/0.01 uF (2b note) vs 2.7 kohms/0.001 uF (2a - R7/C13).

B Log Det R6 value is 75 ohms (3 note) vs 100 ohm (1) on page 5.

C. VGA R2 value is 3.0 kohms (2b) vs short (1) on page 8.

In the Expanded Log Amp configuration, since the MagVolts source for ADC is VGA rather than Log Det, can the J2 Log Det connector be used as the source for VGA Fdbk input rather than Log Det J2A?

Larry, W2HHV

7976. Re: Log Det/VGA Ckt Values for Expanded Log Amp

Yahoo group: spectrumanalyzer (2011)

From: Sam
Topic: 7975 Message: 7976

Larry,
The Expanded Log Detector has gone through some evolution, so there are various schematics floating around. Originally, it required modifying the Log Detector to split the detector output to two SMA connectors. Then I modified the VGA so the Log Detector could be used in its original form, with the detector output run to the VGA as feedback, and the VGA having an extra output to run that same signal to the ADC. The most current schematic is the one on my web site called "Even more updated Schematic and Layout", and can be downloaded here:

<http://www.wetterlin.org/sam/SA/ExpandedLogDetect/SimpleExpandedLog.zip>

The present arrangement adds the VGA and noise filter in front of the standard Log Detector. But it is also possible to change R6 on the Log Detector to 100 ohms to increase the RF output level. You also have a choice between a fixed noise filter or the switchable one. The latter should give a bit more low end range with narrow RBW filters. I have not actually built the switchable noise filter as currently designed. I built and am using an earlier, more cumbersome version, though it works well.

When using the Expanded Log Detector, the IF2 amp can be replaced with a 28 dB version that is also on my web site:

<http://www.wetterlin.org/sam/SA/ExpandedLogDetect/IF2Amp_OPA847.zip>

It will draw about 45 mA less current than the original IF Amp, and provides 12 dB less gain to avoid overloading RBW filters. But if you have the original IF Amp, you can use it, adding some output attenuation if you want to reduce the gain.

Sam W.

The free ExpressPCB software does not a function to create gerber and drill files. That is why we could not make the board from other PCB factory, which may be much cheaper than expressPCB.

Yep, I know.

I'm willing to spend time transferring some of the stable PCBs (such as the MOB, PLL, etc) to eagle, or some other PCB cad program so we can get much cheaper boards. I offered this before, but people seemed resistant to the idea. I know that Sam and Scotty like to use express PCB, so for the in-flux designs it doesn't make sense.

Speaking of boards, is there a pcb file for the RBW board that combines the 4 filters and switch onto one board? I would sure link to get away from using all those SMA connectors and jumper.

Thx

Ed G

7980. Re: Circuit Board Source

Yahoo group: spectrumanalyzer (2011)
Date: 2011-04-21 18:58:20 UTC
From: Sam
Topic: 7968 Message: 7980

See RBW_Filter_Board.pcb in the Files section. This combines the RBW filter switch, two ceramic filters, a 5-crystal filter (Scotty's schematic) or 3-MCF filter (per Lin's postings). Three direct-soldered coax jumpers are necessary on the board, but all other connections are done with traces.

Jim Hontoria made up a couple of these boards, with some modifications. He may still have an extra.

There is no unified schematic for this board, but each section uses the same numbering as its original schematic. There are a few changes in the filter switch relating to elimination of the connectors, and a few SMT jumpers are needed to complete the connections to some filters, but all that should be clear from the board. The amplifilter is modified from the original, but the schematic for the amplifilter in the Files section contains both the original and modified schematics. The modifications simply delete the regulator, since it taps into the +5V supply of the RBW switch. I noticed on Jim's version of this board, he preserved the +8V regulator for the amplifilter.

Will,
I like ExpressPCB because it is simple and fast, but I'm certainly not opposed to converting the boards to a standard CAD format, especially, as you say, for boards whose design is well settled. Eagle would be a good choice, because a lot of manufacturers use their format in addition to Gerbers. I checked out iTead, which you mentioned, and noted that they have a very simple way to use Eagle files. I have Eagle installed on my computer, though I don't want to redo the layouts myself.

A lot of manufacturers, which I believe includes iTead, don't allow combining two boards onto one PCB. They seem to think you are taking advantage of them, though I don't see how it is any of their business what you put on your board. That can reduce the apparent price advantage of these outfits. On the other hand, it would be nice to obtain individual boards to avoid the need to cut a large board into pieces.

Sam W.

? I use KICAD for my designs.? It is FREE, open source, and works on Windows, Linux, and OSX.? It will output standard Gerber files which any manufacturer.? I think whatever CAD system you use should be available free so others can modify for their own use.
I do not order from Far Circuits because of the lack of plated thru holes.

I totally agree... but...

I use eagle almost every day. It's not open source, but it's still free to use for hobbies. I can't justify the expense of learning a new CAD program, and recreating all of my libraries. To be honest, I've got a license of Altium Designer, which is one of the nicest electronic design programs there is... but I don't really use it due to the learning curve. If you'd like to take the charge on transferring the designs using KICAD, I think that would be great!

Hi Scotty,
Is the 2N7002E a drop in replacement? How about the internal resistors in the MUN2211?

Jim, W1JGH

Eagle will also produce gerbers, but many manufacturers take the Eagle files directly. I used to use Eagle a lot, and loved it. I tried KICAD, and never really took to it. But I'd say that if anyone wants to convert the layouts, they can use any program they want!

I also recall someone saying that once you order boards from ExpressPCB, you can get the gerbers from them. I don't know whether that is true, but it would be worth checking.

Jim,
In theory that should work, but in theory the MUN2211 should have worked better than it does. I think what Scotty was looking for is someone to actually try out the FET. Those resistors are for limiting the current load on the ADC and setting the on/off threshold, and shouldn't be needed for the FET.

Yes, I bought the Gerbers from Express years ago for the original N2PK VNA boards. Giancarlo then had boards made in EU for pennies on the dollar. At that time after Express had made the originals, you could purchase the Gerbers from them for $75.

W4ZCB

Eagle will also produce gerbers, but many manufacturers take the Eagle files directly. I used to use Eagle a lot, and loved it. I tried KICAD, and never really took to it. But I'd say that if anyone wants to convert the layouts, they can use any program they want!

If we had gerber files, could they be imported and modified in Eagle, KICAD or some other program? I'm guessing you could make simple modifications with some sort of graphics editor, but wouldn't be able to recreate the board as a collection of traces and pads that could be individually moved, deleted, etc.

Hi Guys,

I have placed a couple of fairly large (by my standards) orders with PCBexpress. Let me see if they will provide me with the gerbers. It would be for the full panel and for the filter switch board as those are the only orders I have placed with them.
If I can get my hands on them, I will upload them to the files section of the group website if you guys think that is where they belong.

Bob

Sam,

Yes and no.

You can make some simple changes, like adding a bit of copper here and theres, but anything large would be next to impossible. The gerber format is truly bizarre. It also doesn't contain any net list information. It is nothing more than "apertures," which are basic shapes like a square or circle, and paths which are commands like: open the shutter, move to this x,y, close the shutter, etc.

I've spent about 20 minutes on the MOB while watching TV and it's getting close to being done. I have one question about the coax connections though. It has a quality that I'm not sure how to reproduce. On the construction page http://www.scottyspectrumanalyzer.com/construction.html it looks like the signal pad has different annulus diameters on one side of the board than the other. Is this true, or is it just a fluke?

Thanks,
- Will

7994. Re: Circuit Board Source

Yahoo group: spectrumanalyzer (2011)
Date: 2011-04-22 14:44:39 UTC
From: Sam
Topic: 7968 Message: 7994

Sounds a lot like "turtle graphics". If you have the gerber file for a PCB made up of many smaller boards, is it feasible to create several gerber files, each containing just a single board? Sounds like that would be difficult.

Ideally, the coax holes would have no annulus on the bottom. It's probably necessary to make the bottom match the top, as it is in ExpressPCB, which is OK because the bottom pad is easily removed by hand with a couple of twists with a drill bit.

7995. Re: Circuit Board Source, Holophase OmniGlyph

Yahoo group: spectrumanalyzer (2011)
Date: 2011-04-22 16:16:29 UTC
From: Greg Broburg
Topic: 7968 Message: 7995

Hello group;

I have watched this discussion about PCB layout tool issues for several years. I have been a user of Holophase Circad/OmniGlyph for many years. In addition I have supported many new users who have wanted to learn this program. I understand that ExpressPCB is now a defacto standard for our group. These files can be, perhaps already have been converted to Circad format.

The demonstration version of OmniGlyph is available free on the www.holophase.com website and is mostly complete in that it allows an unlimited PCB/schematic/drawing file capture. These files are generally open to saving and sharing among the users and are not tied to any PCB production company. The issue of post production to Gerber generation is the issue which requires a little bit of money in one way shape or form to make up for the idea of using the demo program concept as a starting point. I have talked to Fred Lehman owner of Holophase about an idea to make the demo program a foundation for people who want to corroborate on this idea.

Any thoughts?

Regards;

Greg

Sam,

Yep, you've got the right idea. It is possible to make many boards from a larger one. The issue is mostly that of deciding what the origin is. It's also possible to make a larger panel from many designs.

I'll look into making the coax connections in some different ways, then I'll bring it up to the list for opinions...

- Will

From: william sprowls
Topic: 7968 Message: 7997

Hi William,
  That is not a fluke. We would like the smallest pad size on the ground plane side (bottom) and a larger size on the circuit side (top). This is so that the smaller pad can be easily removed with a hand held drill bit when using the "direct connection" method of attaching coaxial cables.
Scotty

Sam,
Yes and no.
You can make some simple changes, like adding a bit of copper here and theres, but anything large would be next to impossible. The gerber format is truly bizarre. It also doesn't contain any net list information. It is nothing more than "apertures," which are basic shapes like a square or circle, and paths which are commands like: open the shutter, move to this x,y, close the shutter, etc.
I've spent about 20 minutes on the MOB while watching TV and it's getting close to being done. I have one question about the coax connections though. It has a quality that I'm not sure how to reproduce. On the construction page http://www.scottyspectrumanalyzer.com/construction.html it looks like the signal pad has different annulus diameters on one side of the board than the other. Is this true, or is it just a fluke?
Thanks,- Will

Hi Greg,
 The group has not really set the "defacto standard" for Express. Actually, it was me who has released all of the MSA designs in Express. The reason for that is that it is soooooo easy to use. I have tried Eagle, Circad, and a couple of others. They were not as "user friendly" as Express. Circad just sucks. It is DOS based trying to work in Windows.
 There is certainly no reason someone cannot "redo" the boards in another CAD program. The only thing is, there is the potential for "slip-ups" during the change-over process. This has occurred and I was not able to prevent it. Even though Express is much more expensive than everyone else, it is a very convenient program, allowing "cuts and pastes" of different boards to create a larger panel. I will continue to use Express, and any future modifications will be in Express. A change now would require an extensive update to many existing web pages.
Scotty

Hello group;

I have watched this discussion about PCB layout tool issues for

several years. I have been a user of Holophase Circad/OmniGlyph

for many years. In addition I have supported many new users who

have wanted to learn this program. I understand that ExpressPCB

is now a defacto standard for our group. These files can be,

perhaps already have been converted to Circad format.

The demonstration version of OmniGlyph is available free on

the www.holophase.com website and is mostly complete in that

it allows an unlimited PCB/schematic/drawing file capture. These

files are generally open to saving and sharing among the users

and are not tied to any PCB production company. The issue of

post production to Gerber generation is the issue which requires

a little bit of money in one way shape or form to make up for the

idea of using the demo program concept as a starting point. I

have talked to Fred Lehman owner of Holophase about an idea

to make the demo program a foundation for people who want to

corroborate on this idea.

Any thoughts?

Regards;

Greg

On 4/22/2011 8:14 AM, William Dillon wrote:

Sam,

Yes and no.

You can make some simple changes, like adding a bit of
copper here and theres, but anything large would be next
to impossible. The gerber format is truly bizarre. It
also doesn't contain any net list information. It is
nothing more than "apertures," which are basic shapes like
a square or circle, and paths which are commands like:
open the shutter, move to this x,y, close the shutter,
etc.

I've spent about 20 minutes on the MOB while watching
TV and it's getting close to being done. I have one
question about the coax connections though. It has a
quality that I'm not sure how to reproduce. On the
construction page http://www.scottyspectrumanalyzer.com/construction.html
it looks like the signal pad has different annulus
diameters on one side of the board than the other. Is
this true, or is it just a fluke?

Thanks,
- Will

If we had gerber files, could they be imported
and modified in Eagle, KICAD or some other
program? I'm guessing you could make simple
modifications with some sort of graphics editor,
but wouldn't be able to recreate the board as a
collection of traces and pads that could be
individually moved, deleted, etc.

From: Sam
Topic: 7968 Message: 7999

I think it could be useful to have the boards available in another format, but it wouldn't be necessary to supplant the "official" ExpressPCB boards. For example, if just the MO, PLO, DDS and mixer boards were available in a gerber-friendly format, it might be feasible for someone to order a bunch at low cost and stockpile them. Or it might make it easier for non-USA builders to acquire the boards at a reasonable cost. And it would certainly make it easier to obtain individual boards, without the need to cut apart a large panel.

ExpressPCB's biggest weakness is the way it handles solder mask and silkscreen. While you can cut and paste to assemble small boards into a big one, the solder mask layer doesn't get copied or moved unless you do a separate operation on it, making it easy for the mask layer to become out-of-register. And the smallest available font for silkscreen is too big to make silkscreen useful on densely-packed boards, which are exactly the boards that can benefit from it. Personally, I am happy without silkscreen, but a lot of people seem to like it. The PLO boards in particular would probably be much easier to assemble if they had silkscreen labels.

So I wouldn't favor switching away from ExpressPCB, but I think it would make sense to supplement ExpressPCB for at least some of the boards.

(BTW, I mentioned I had tried KICAD, but now that I think about it, what I tried was Circad. It seemed awkward to use, but maybe I didn't get far enough along in the learning curve.)

Hello Scotty;

I am sorry that you feel that way about Circad.
OmniGlyph is a new program that was built from
scratch to run in the Windows environment. As
a user coming from Cadstar OrCad and AutoCad
I would have to say that Circad was excellent. I have
done now more than one hundred designs in Circad
/ Omniglyph and capture many designs into the
schematic features for electronic archiving.

I cannot imagine using ExpressPCB as a serious
CAD package but I understand why it is used.

Ed
I just made such a combined RBW board for several pieces, with latest MSA collections. Yes, the purpose is to get rid of the SMAs.
I put a photo here:
http://groups.yahoo.com/group/spectrumanalyzer/photos/album/608125393/pic/179096224/view?picmode=&mode=tn&order=ordinal&start=41&count=20&dir=asc

I agree with Scotty that the ExpressPCB is easy to learn. Also if we convert to other program, we need to try several times to get rid of those errors from the conversion. A lot of people in this group have to learn a new software?

I'm about ready to switch back to USB. Mxr buffer famps working. Got the combo RBW board in place. Love the amplifilter although I have an issue with the Xnarrow filter that flattens and spreads out the zero hump horrendously. I'll get back to that later. My VGA seems to be working fine although I see that you have been discussing related issues. YIG is still work in progress, about ready to tackle the software.

Jim,
Perhaps your issue with the XNarrow filter is sweep speed. If you scan too fast it can do what you describe. Try reversing the sweep direction to see if the shape changes; if so, the speed is too fast. If using AutoWait, there should be no issue as long as you specified your filter capacitors correctly.

A somewhat related issue: I was doing scans from 100 kHz to 100 MHz and was getting strange things at the low end. Turns out I was using my 400 kHz RBW filter, which I rarely use but I had been testing it. This of course smeared the zero hump across a couple hundred kHz. It took me a while to realize what was happening, and then I felt like an idiot.

Let us know how USB works. I'm particularly interested in its sweep speed compared to the parallel port.

Sam W.

I run som sweep checks to establish a baseline before I change over.

8006. Re: [spectrumanalyzer] PLO2 output distortion

Yahoo group: spectrumanalyzer (2011)
Date: 2011-04-23 18:56:12 UTC
From: Jurgen
Topic: 7949 Message: 8006

I am testing the PLO2 module using a 6V regulator and find that the 1GHz output has quite a bit of distortion.
According to the scope FFT the 2nd harmonic is down by about 10 dB.
Has anyone had a similar experience.
My output level ~+10dBm into a 50 ohm resistive load.

You are right on target with the data sheet, which shows second harmonic near -10 dBc for the 1-5V tuning range.
Sam W.

20GHz direct coupling. I am probing with a 2.5 GHz probe.

8011. Wire Resistance

Yahoo group: spectrumanalyzer (2011)
Date: 2011-04-24 14:29:16 UTC
From: Sam
Topic: 8011 Message: 8011

I built a relatively crude shunt fixture consisting of two 49.9 ohm resistors (one leading from the input and one leading to the output), both connected to a grounded 10 ohm resistor. The DUT connects to the common connection of the resistors. This is a 16.7 ohm shunt fixture that is optimal for measuring small resistances.

I did Reference calibration, using a 100 ohm resistor as the reference, and measured the resistance of a short piece of #30 wire. The resistance was extremely small--0.012 ohms at 1 MHz and 0.043 ohms at 25 MHz. Yet all indications are that they were accurately measured within a couple of milli-ohms.

I posted a photo of the scan and some explanatory comments:

<http://groups.yahoo.com/group/spectrumanalyzer/photos/album/252922278/pic/1294717754/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc>

Measuring resistance with a shunt fixture is very similar in concept to 4-wire Kelvin measurement of DC resistance.

Sam W.

8012. Re: [spectrumanalyzer] Circuit Board Source, Holophase OmniGlyph

I've finished the first draft of the Master Oscillator board in eagle. I've copied essentially exactly the coax pad that Scotty has designed. The annular ring on the back side is the minimum diameter allowed by most PCB houses (20 mils). I've taken some liberties on the design. I copied exactly the schematic, but omitted the optional components. At some point, I'll have some of these made, and when I do, I'll mail some of them to people that want to beta test it.

I've documented it on my blog's master oscillator page:

http://alternet.us.com/?page_id=753#eagle

> >
> > Hi Greg,
> > Â The group has not really set the "defacto standard" for Express. Actually, it was me who has released all of the MSA designs in Express. The reason for that is that it is soooooo easy to use. I have tried Eagle, Circad, and a couple of others. They were not as "user friendly" as Express. Circad just sucks. It is DOS based trying to work in Windows.
> > Â There is certainly no reason someone cannot "redo" the boards in another CAD program.Â The only thing is, there is the potential for "slip-ups" during the change-over process. This has occurred and I was not able to prevent it. Even though Express is much more expensive than everyone else, it is a very convenient program, allowing "cuts and pastes" of different boards to create a larger panel. I will continue to use Express, and any future modifications will be in Express. A change now would require an extensive update to manyÂ existing web pages.

8013. Re: Circuit Board Source, Holophase OmniGlyph

Yahoo group: spectrumanalyzer (2011)
Date: 2011-04-25 12:59:01 UTC
From: Sam
Topic: 7968 Message: 8013

Looks very nice. It would be a good idea to keep the board clear of solder mask for a 40 mil boundary on top and bottom, for soldering fencing. In fact, I would suggest keeping the entire bottom clear of solder mask, except where you need it as backing for labels.
Sam W.

Sam,

After looking at the latest VGA/NF schematics, I'm understand what to change on the VGA schematic (Rev 1.1, 9/10/10) to build the Rev 1.1, 9/25/10 version of this module. i.e.; Since the VGA PCB on hand is the "VGA 5/16/08" version, the following modifications apply:
1. Omit C10A and R2B; wire jumper R2B pads,
2. Add C10, 10 nF,
3. Change following resistor values: R2 = 10K ohms, R2A = 27K ohms.

And the related usage of Scotty's Log Detector is:
R6 = 100 ohms, and J2 only is used to interface to VGA Fdbk input, J2A circuitry not needed.

The NF PCB on hand is marked NF 5/10 but I ordered parts based on values on the Rev 1.2, 9/10/10 schematic which has a PCB file marked as NF 9/10. Since the latest NF schematic (Rev 1.2, 11/12/10) is significantly different, I need to "stay the course" and update the NF 5/10 PCB to the 9/10/10 schematic. So far, the only change I located is a trace cut and jumper add to move U1-6 Vdd connection from +5 vdc to +10 vdc voltage source.

Do any other mods apply to NF 5/10 PCB version?

Larry, W2HHV

These PCBs on hand are from the panel offered in Aug 2010 Group Buy.

> The Expanded Log Detector has gone through some evolution, so there are various schematics floating around. Originally, it required modifying the Log Detector to split the detector output to two SMA connectors. Then I modified the VGA so the Log Detector could be used in its original form, with the detector output run to the VGA as feedback, and the VGA having an extra output to run that same signal to the ADC. The most current schematic is the one on my web site called "Even more updated Schematic and Layout", and can be downloaded here:

> The present arrangement adds the VGA and noise filter in front of the standard Log Detector. But it is also possible to change R6 on the Log Detector to 100 ohms to increase the RF output level. You also have a choice between a fixed noise filter or the switchable one. The latter should give a bit more low end range with narrow RBW filters. I have not actually built the switchable noise filter as currently designed. I built and am using an earlier, more cumbersome version, though it works well.

Larry,
The changes on the VGA are as you describe, affecting only the feedback path from the log detector.

If you actually have Scotty's log detector PCB, the J2a components aren't even present, but if you have a board containing them you are correct to omit them. The change of R6 to 100 ohms is correct.

Your "old" switched noise filter will work fine (that is the one I am using), with the trace change you describe. I didn't do this, but it would be a good idea to make the new +10V connection for the op amp through a resistor (4.7-10 ohms) or a ferrite effective at 10.7 MHz. I also ended up with R5=680, R4=470 which may or may not be an improvement. The schematic also does not show the complete jumpering of the two filter outputs (marked N and W for narrow and wide) to the switch. How you do it depends on which noise filter you want to use with which RBW. I used the wide noise filter for the two widest RBW (paths 1 and 2) and the narrow noise filter for the others (paths 3 and 4). This means the wide filter goes to pins S1 and S2 of U2, and the narrow filter goes to S3 and S4. Each pin S1-S4 connects to a pad for jumpering. The PCB connects the pads for S2 and S4 so I had to cut that connection.

Sam W.

I really have built many PCB boards, if you need it, please check my eBay selling items.
This is the first time that I try to sell some items on eBay.

Thanks.

following are the boards which I can provided.

1) VCO_2G_3G board U$8. fully tested.
2) VCO_2G board U$6. fully tested.
3) ADF4350 board U$6. partial tested.
4) ADF4350 or VCO control board U$8. partial tested.
5) adl5513 PCB board U$6. fully tested.
6) dds_107 PCB board U$8. fully tested.
7) MO_64 board U$6. fully tested.
8) PDM board U$6. not tested.
9) AMP_ALC board U$6. not tested.
10) Attenu board U$6. not tested.

8020. Express Miniboards

Yahoo group: spectrumanalyzer (2011)
Date: 2011-04-28 18:16:26 UTC
From: william
Topic: 8020 Message: 8020

Hi All,
It has just come to my attention that Express PCB has another option to their Miniboard service. It is called MiniBoardPro. It is the same service as their Standard Miniboard, but provides silkscreen and soldermask layers.
The reason I bring this up is that my board designs have been developed with only the Standard Miniboard in mind. If you order my designs using MiniBoardPro, ground layers will likely be covered in soldermask. Electrically, this is not a problem. However, when you attach some components and fences, you will have to scrape away the soldermask for soldering. I just wanted to warn you before you start to curse me.
Express's new MiniBoardPro service is great, but my PWB designs will need modification to fully utilize their benefits.
Scotty

Topic: 8020 Message: 8021

The necessary modifications for solder mask aren't too bad, primarily involving putting 40 mil wide pads around the outside of the board (solder mask is automatically blocked on actual "pads" and "vias" but not on traces or filled planes) and blocking solder mask on the entire bottom. Pads also have to be placed wherever there would be internal fencing. Boards designed to have SMA connectors slide on the side of the board (this doesn't include any of the standard SLIMs) also need mask blocked for their center pins and legs.

The biggest problem has to do with silk-screened text. You usually have to move the text outside the component boundary (it won't print on bare pads, and you don't want it there anyway) and there is usually very little room to put it, since ExpressPCB's minimum font size is fairly large. You will end up simply "hiding" about half of the component labels, which eliminates much of the advantage of silk-screening.

8022. Which coax to use ?

Yahoo group: spectrumanalyzer (2011)
Date: 2011-04-29 01:08:09 UTC
From: jjkirb1
Topic: 8022 Message: 8022

Hi, can any one direct me to web page which talks about, which type of coax to use to connect up the SLIM's for Scotties MSA ETc.. It looks like in the pictures that couple of the cables are UT 141 rigid coax. Any help would be apreciated.

8023. Re: Which coax to use ?

The rigid/semi-rigid/semi-flexible terminology is ambiguous. I go with the terminology copper-tube-shield and conformable (which is the tin-dipped shield). (There is also aluminum-tube-shield and silver-plated-copper-tube shield, which I lump with copper-tube-shield.) The basic size choices are 0.141 inch and 0.86 inch (sometimes called 0.85 inch). They are all good, but the ideal is probably to use copper-tube 0.141 for the PLO connections (>1 GHz) for low loss and absolute max shielding, and conformable 0.85/86 for <1 GHz, for the flexibility. For the cavity filter connections, some form of 0.141 is probably best. If you could be sure you wouldn't have to bend and re-bend it, the copper-tube would be best; otherwise the conformable is best.

Conformable is flexible and can be re-bent several times, but beware of twisting it. That is, if you have it bent at 90 degrees parallel to the bench, and want it 90 degrees toward the bench, don't twist it; rather, you should straighten it and re-bend it.

For the 10.7 MHz connections, you can even go with plastic jacketed non-dipped coax, but be sure it is double shielded (typically, a braided shield plus an aluminum foil wrap).

In my MSA, I use the conformable coax everywhere, and it works well. But if I did it again I would use the copper tube stuff for the PLOs, just to be safe.

Some people call the copper-tube-shielded coax "semi-rigid". If that is semi-rigid, I would like to see what "rigid" is--perhaps something encased in a 1/2" plumbing pipe.

Hi Sam,
 In my day (long ago) "rigid" meant hard waveguide. But, you are right. The terminologies today are very ambiguous.
 I would advise against the silver plated aluminum semi-rigid unless you are very good at soldering. You get one shot at this stuff. With too much heat, the silver will leach and leave the bare alu. Then, it won't solder again.
Scotty

8026. Low Z Measurement; Dip Meter

Yahoo group: spectrumanalyzer (2011)
Date: 2011-04-29 16:11:49 UTC
From: Sam
Topic: 8026 Message: 8026

I put together some documentation on the fixture I used to measure RF wire resistance. It is optimized for the range 0.01-10 ohms, though it will measure higher impedances:

<http://www.wetterlin.org/sam/SA/Operation/Fixture_LoZ.pdf>

With a slight modification to add a coupling coil, this fixture can be used as a dip meter to find resonant frequencies:

<http://www.wetterlin.org/sam/SA/Operation/Fixture_DipMeter.pdf>

8027. Where Used for Female Contacts

Yahoo group: spectrumanalyzer (2011)
Date: 2011-04-30 16:02:04 UTC
From: lh1907
Topic: 8027 Message: 8027

I am starting to build the MSA modules using the parts from Cash Olsen's Discrete and IC Group Buy of Spring 2009. Would someone describe where the contacts (items 68 and 69 on Cash's parts list) are used?

#68 Qty 125, Conn Term Female 22-24AWG Gold (90123-0112); and
#69 Qty 24, Conn Socket 22-24AWG .100" Gold (90119-2110).

The Molex P/N is in parenthesis. The specs on Mouser and Molex sites provided no basis for deciding which contact is used on which 0.025 SQ Conn Header position. Both contacts are gold plated but prices are significantly different: Per 100 costs are $6.70 (#68) vs $21.00 (#69).

#68 part is rated for 250v at 3 amp. Found not electrical spec for #69 contact.

Adding up the total number of conn housing positions (127), it appears Cash has include some spare of each type contact for build breakage.

Larry, W2HHV

On Digi-Key, the 0112 part is the plastic housing for the contacts, and the 2110 parts are the actual connectors that crimp to the wires and fit inside the housing. Both are the Molex C-Grid III series. None of the header pins carry enough current that current capacity would be a concern. I used the C-Grid III connectors everywhere.

Sorry for the typo. The correct P/N for item 68 part is:

#68 Qty 125, Conn Term Female 22-24AWG Gold (16-02-0087).

Corrected P/N in original e-mail of this message.

No obvious difference between two parts except internal two wiper blades are on opposite sides (relative to open side of U for wire crimp). Item 68 contacts are on a bandoleer (25 contacts per strip, 5 strips total). Item 69 contacts are in a plastic bag; loose single contacts.

Not very objective, but unless someone has more insight, I'll use the item 68 part everywhere. i.e., Based on total qty.

The #68 parts are C-Grid, vs C-Grid-III for the #69 parts. I think I remember seeing something in the Digi-Key description to the effect that C-Grid parts don't mate with C-Grid-III parts. Since I couldn't see any difference I decided I was just going to pick one series and stick with that. So that's what I did until I ran out of the headers and housings, at which point I used C-Grid-III connectors in some housings I had gotten from Jameco, with header pins I also got from Jameco. With the wires crimped into the connectors, I could not slide the connectors quite far enough into the housing to lock in place. When plugged onto the header, it made a very tight connection, which seemed good until I realized one of the connectors had been pushed partially out the back of the housing. I got that back into place and everything is fine.

The moral is that these parts don't seem to be as standardized as one would expect.

Dealing with connectors is always the worst part of any electronics project.

Thanks for the insight Sam. I'll try a "mating" test case before using the C-Grid contact (item 68 part) and the qty on hand should cover the total MSA build. If the C-Grid contact (item 68 part) fails the mate test, I'll confirm the C-Grid-III contact (item #69 part) has no mating problems before using it on end item MSA Modules and ordering more contacts.

8032. How to compare two curve with SA+TG mode or VNA mode

Yahoo group: spectrumanalyzer (2011)
Date: 2011-05-04 01:42:43 UTC
From: inlinebeginner
Topic: 8032 Message: 8032

Sam
The comercial VNA can compare two curves by displaying both memory&data (first data->memory), can we do similar work on MSA? The comparison function is very useful when tune circuit. Before change the part, a curve can be scanned and saved to memory, after the part is changed, we can see the difference between the memory and current scan.
Thanks
Lin

8033. Some extra PCBs on eBay

Yahoo group: spectrumanalyzer (2011)
Date: 2011-05-04 11:28:07 UTC
From: taishan_ma
Topic: 8033 Message: 8033

hello,

I have done some PCBs based on s53mv's projects and scotty's projects, and have put some extra PCBs on eBay. Maybe there have some of them that you needed.

Please let me know if you need any of them. You can also visit my poor website: http://www.qsl.net/bg6khc/.

Tnx and 73!

From: taishan_ma
Topic: 8033 Message: 8034

You can reach them at:
http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=220778955579&ssPageName=STRK:MESELX:IT#ht_483wt_1158

There about 12 types PCBs that I have put on eBay, actually I have also some other type's PCBs developed. However, I am limited put more items on eBay as a beginner.

Tnx and 73!

Lin,
Halt after you have the reference scan and use menu Options->Reference Lines, which lets you create reference lines in various ways. You want to create one by saving the current data. In addition, you can choose to simply display the line (which you probably want) or to add/subtract the line to/from future scan data. The line will be displayed, but you can't put markers on it. If you put markers on the main graph, as I recall the value of the reference line at the currently active marker will be displayed below the graph.

Menu Options->Appearances lets you customize the color of reference lines, just as you can for the regular graph lines.

If you elect to subtract the reference data from future scan data, you effectively can achieve calibration in SA+TG mode, with the reference scan being the calibration data. This subtraction is exactly what is done in Transmission mode to apply calibration. But if you do this in SA+TG mode, you will have "used up" the reference line feature for calibration, and can't do any additional reference lines. So if you want calibration and reference lines you should use Transmission mode.

At one point I was going to create a Snapshot feature to save a graph image in a new window for comparison with subsequent scans. But I decided it is just as easy to use a separate graphics program. In particular, I use the freeware screen capture program Greenshot. When you hit the Print Screen button, Greenshot lets you select the area of the screen to copy and then copies that to a new window where it can be used for visual comparison, or saved to a file. It will also let you add text, lines, arrows and highlighting. Of course, this graphics approach does not let you actually overlay two scans on the same graph, as you can with Reference Lines.

A diversion: SA+TG mode accomplishes nothing that Transmission mode can't do, and exists only for those who are more comfortable thinking of the MSA as a spectrum analyzer than as a network analyser. If your build does not include the PDM, VNA Transmission mode still operates, but without phase, and becomes a scalar network analyzer (SNA). At one point, I actually labeled it SNA when the PDM was not present, and did not even have SA+TG mode. A scalar network analyzer is really SA+TG with calibration. However, actual devices sold in the past as SNAs were apparently clunky instruments that pre-dated full VNAs, and the term has bad connotations.

Same
Here is what I did in SA+TG mode:
1) Halt at end, Options>> reference lines
2) Choose "USE Current Data", "Data and Ref", and "Do trace for Right Axis">> OK
3) Change my circuit, and click Continue
I see two lines on my screen. One is the reference line, other one is the current scan.

Thanks.
Lin

8038. Marker Interpolation

Yahoo group: spectrumanalyzer (2011)
Date: 2011-05-08 16:01:03 UTC
From: Sam
Topic: 8038 Message: 8038

In VNA modes, it is often handy to place markers between actual data points, as you would do to find where phase crosses zero if there is no actual data point actually at zero phase. In that case, the software interpolates the data from the neighboring data points. There are some interesting issues that arise, discussed here:

<http://www.wetterlin.org/sam/SA/Operation/MarkerInterpolation.pdf>

That document also illustrates some useful techniques with the MSA, such as MouseOver on the Smith chart, and the use of phase graphs with a range greater than 360 degrees.

I have updated the info on my web site regarding construction and characterization of calibration standards. There are several documents, with some overlap, combined in a zip file:

<http://www.wetterlin.org/sam/SA/Operation/CalStandards.zip>

Version 116 of the software contains a new method for describing cal standards, which is a little more flexible. Generally, though, I have gotten good results treating the calibration standards as being ideal.

Some time ago, we tested some standards made from Amphenol RFX connectors, and others made from certain Molex connectors. The characteristics of the Open and Short determined in those tests could be used by others using the same connectors. The characterisics of the Loads probably vary enough from build to build that a standard description is not suitable, but if you have a way to measure your Load on a commercial VNA these documents will help convert that data into a suitable description.

I added the RFA-1 buffer AMP between Mixer3-J3 and PLO2-J3, it does not help to reduce this spurs. However, after I added one more buffer AMP between PLO1-J2 and Mixer4-J1, this spurs is removed (it was -90dBm, now it is under -108dBm, I could not see). I tried, it needs two buffer AMPs, i.e, the leakage goes through two pathes.
The 10.111MHz spur of the 1kHz RBW path is also removed with above buffer Amps.

Scotty and Sam
Looks like these two leakages randomly cancel each other, that is why we saw the spur amplitude is up and down, if we put only one isolation buffer amp in, the spur stops jumping and the scan curve becomes clear and stable. Does this mean if we put two buffer amplifiers it will help for the phase accuracy? Or is it helpful for lower signal phase detection?

Topic: 7235 Message: 8043

The isolation amp between PLO2 and Mixer 3 reduces the level of the "zero response", but in my MSA, as apparently in yours, it did not affect the 10.7 MHz spur. My internally generated spur at that frequency is fairly low, about -105 dBm. However, if you are running the TG signal through a DUT to the MSA input, there is an additional spur at 10.7 MHz that is caused by LO2 or LO3 (I forget which) in the TG signal. So if you are looking for internally generated spurs, you want to have terminations on the TG output and MSA input.

It sounds like you have tracked the remaining spur to leakage from Mixer 4 back to PLO1. Perhaps your Mixer 4 is especially leaky for some reason. If your buffer amp eliminates the spur, go with it.

This "10.7 MHz" spur actually occurs at whatever your RBW frequency is specified as. It is certainly possible that it comes from more than one source, as you say. This spur definitely affects phase accuracy if you are at exactly 10.7 MHz, if your actual test signal is within 40 or 50 dB of the spur level. But it doesn't affect phase accuracy at any frequency outside the approximate range of 10.7 MHz +/- the RBW bandwidth.

A simple test for the phase effect is to do a zero-width scan at the RBW frequency in Transmission mode, but with the MSA input coming from an external signal generator. Use the Narrow video filter. Start with a signal near -100 dBm, and watch the phase graph. If it is a wavy line, the spur is having an effect. Making the signal stronger will reduce the waviness. Adjusting the wait time affects the period of the waves. I believe the waviness comes primarily from the gradual phase change caused by the fact that the signal generator frequency is (almost certainly) slightly different from the MSA frequency. If they are too different, you'll probably get a mess. If they happen to be identical, this test may not show anything. I think mine are within a couple Hz of each other.

The above test can identify a spur even if it is well below your minimum visible signal.

The spur at 10.7 MHz might seem like a problem because a lot of work is done in that area. However, if you are scanning a 10.7 MHz filter, the filter output will be strong and the spur will have no effect. If you scanned a 10.6 MHz filter, you might see the spur as a blip on the base of the response; it would show up as a blip in the phase graph too, but you normally don't care about phase outside the pass band.

Sam W.

From: Sam
Topic: 7235 Message: 8044

Lin,
I just realized that you posted photos of the responses. Apparently the LO2 isolation amp did have some effect, but still left a large spur caused by the other leakage path. I haven't analyzed it thoroughly, but it seems odd that the two leakages combine to produce a spur that jumps around. That would indicate that they don't have a stable phase relationship and sometimes interfere constructively and sometimes destructively. I would have thought the phase relationship would be stable.

I mentioned the spur that arises at 10.7 MHz when the TG is connected to the MSA input. I believe that arises from LO3 and its harmonics in the TG. At 10.7 MHz, LO1=LO2=1024 MHz and LO3=1034.7 MHz. One of the Mixer 1 products will be 2xLO1-LO3, which is 1013.3 MHz, equal to the first IF.

The leakage path you describe lets LO3 leak through Mixer 4 into LO1. To the extent it works its way to the other LO1 connection of PLO1, it goes directly to Mixer 1, and creates exactly the same issue as LO3 in the TG. (Of course, LO3 in the TG can be eliminated with a low pass filter. Not so with LO3 in LO1.)

I suggest you inspect Mixer 4 and PLO1 to see if there is anything that might aggravate leakage, such as a bad solder joint on the mixer or connector pins sticking up in the air.

Sam W.

--- In spectrumanalyzer@yahoogroups.com, "Sam" <swetterlin@...> wrote:
>
> The isolation amp between PLO2 and Mixer 3 reduces the level of the "zero response", but in my MSA, as apparently in yours, it did not affect the 10.7 MHz spur. My internally generated spur at that frequency is fairly low, about -105 dBm. However, if you are running the TG signal through a DUT to the MSA input, there is an additional spur at 10.7 MHz that is caused by LO2 or LO3 (I forget which) in the TG signal. So if you are looking for internally generated spurs, you want to have terminations on the TG output and MSA input.
>
> It sounds like you have tracked the remaining spur to leakage from Mixer 4 back to PLO1. Perhaps your Mixer 4 is especially leaky for some reason. If your buffer amp eliminates the spur, go with it.
>
> This "10.7 MHz" spur actually occurs at whatever your RBW frequency is specified as. It is certainly possible that it comes from more than one source, as you say. This spur definitely affects phase accuracy if you are at exactly 10.7 MHz, if your actual test signal is within 40 or 50 dB of the spur level. But it doesn't affect phase accuracy at any frequency outside the approximate range of 10.7 MHz +/- the RBW bandwidth.
>
> A simple test for the phase effect is to do a zero-width scan at the RBW frequency in Transmission mode, but with the MSA input coming from an external signal generator. Use the Narrow video filter. Start with a signal near -100 dBm, and watch the phase graph. If it is a wavy line, the spur is having an effect. Making the signal stronger will reduce the

waviness. Adjusting the wait time affects the period of the waves. I believe the waviness comes primarily from the gradual phase change caused by the fact that the signal generator frequency is (almost certainly) slightly different from the MSA frequency. If they are too different, you'll probably get a mess. If they happen to be identical, this test may not show anything. I think mine are within a couple Hz of each other.
>
> The above test can identify a spur even if it is well below your minimum visible signal.
>
> The spur at 10.7 MHz might seem like a problem because a lot of work is done in that area. However, if you are scanning a 10.7 MHz filter, the filter output will be strong and the spur will have no effect. If you scanned a 10.6 MHz filter, you might see the spur as a blip on the base of the response; it would show up as a blip in the phase graph too, but you normally don't care about phase outside the pass band.
>

> > > >
> > > > Hi Lin and All,
> > > > Â The 10.7 MHz spur seen during SA with TG Mode or during VNA Mode is created by the combination of PLO 3 and PLO 2. (I call it the I.F. spur because it will occur at the same frequency as the Final I.F, no matter what it is). When the selected sweep frequency point is 10.7 MHz, the PLO 3 is at 1034.7 MHz. This PLO 3 signal passes through Mixer 3 to PLO 2-J3. It then gets coupled to PLO 2-J2. The two signals, PLO 3 and PLO 2 are input to Mixer 2-J1. The mixing action of Mixer 2 creates the difference frequency of 10.7 MHz (1034.7-1024). Therefore, a low pass filter will not help. Besides, the buffer amplifiers inside PLO 2 are already low pass filters.
> > > > Â The only way to decrease this spur is to decrease the amount of PLO 3 power getting all the way to Mixer 2. A very high isolation mixer at Mixer 3 could cure this spur, but I have not looked for a mixer that would make a good candidate for replacement. (the isolation from Lport to Rport should be at least 45 dB). Another fix is to add a buffer amplifier between PLO 2 and Mixer 3, that has a reverse isolation of 20 dB or better.

> > > > Â One other note: I did some extensive modifications of Mixer 2 to better match 50 ohms. There was an improvement in this spur, but it was not significant enough to include any changes to the Mixer 2 design.

Hi All,
 I don't want to hurt anyone's feelings but I must make this comment. Any PWB that is not created from a released SLIM-PWB on the MSA web site is not truly, a SLIM. I'm not saying that other similar releases are not usable.
 I'll be more specific. If you take a released SLIM-PWB and have several made by Express, they are SLIMs. If you take a released SLIM-PWB and convert it to another CAD design for some other PWB house to manufacture, it will be a SLIM, but only if the conversion is 100% accurate. Any change to the pwb design negates its status as a "released SLIM".

It looks like a lot of work went into creating those eBay boards,
but there are a few things that make me wary. The PLO boards have the two outputs fairly close together, which may reduce the isolation. They also have the PLL reference clock connector located far from the PLL chip, increasing the odds of interference between the clock and the outputs. Likewise with the clock on the DDS; I recall that Scotty discovered that some spurs are reduced if you put the DDS clock input as close as possible to the pin, which means you can't use a connector with legs. The SMA connectors on the PLO and several other boards are very close to the edge, which might hamper fencing, and depending on your mounting arrangement might cause connectors on one board to be very close to those on another board. The bottom of the boards is not shown, but hopefully has no solder mask, to facilitate fencing and attachment of coax or connectors. Many of the boards have mounting holes, which you would likely have to cover up to use the normal mounting methods.

Several of the boards, like the mixers, probably need more top ground plane to preserve isolation. I'm not a big fan of putting ground pour everywhere, but in some places it is necessary. Where fencing is needed in the middle of the board, such as the DDS, the ground plane to which it solders should be free of solder mask.

Hi. I have a question you might be able to help me with. I was thinking of adding IC sockets for U1-U4 for the control board do you think this give me any problems? I will be using gold contacts.
Any help would be apreciated, thanks in advance Stephen.

I personally encourage IC sockets.

It is trivial to zap those ICs, and it's nice to be able to replace them as simply as it is to destroy them :)

8049. Re: lot of slim PCB boards on eBay. NOT! Sockets for latch board

Yahoo group: spectrumanalyzer (2011)
Date: 2011-05-10 23:48:05 UTC
From: Sam
Topic: 8042 Message: 8049

Absolutely. Several people have had problems zapping latches, and sockets would make it easier to replace ICs. I wouldn't use sockets on other boards, though.

Long ago, there was a discussion about not mixing tin and gold in the header connections--"fretting" causes tin oxide to end up embedded in the gold, unless you use an anti-oxidant lubricant. So you would actually best off with tin sockets.

By the way, it seems to be common practice to post a message by replying to a totally unrelated message. Bad idea.

There are chip transient overvoltage limiters are available.
I have used AVX series with excellent results.

Something like VC120605VC100 is a 1206 size part
designed for normal operation below 5V6 and clamp
value of 12V.

These need to have short leads to the protection line and
to the ground of the circuit to work right.

I personally encourage IC sockets.

It is trivial to zap those ICs, and it's nice to be able to replace them as simply as it is to destroy them :)

They also have the PLL reference clock connector located far from the PLL chip, increasing the odds of interference between the clock and the outputs. Likewise with the clock on the DDS; I recall that Scotty discovered that some spurs are reduced if you put the DDS clock input as close as possible to the pin, which means you can't use a connector with legs. The SMA connectors on the PLO and several other boards are very close to the edge, which might hamper fencing, and depending on your mounting arrangement might cause connectors on one board to be very close to those on another board. The bottom of the boards is not shown, but hopefully has no solder mask, to facilitate fencing and attachment of coax or connectors. Many of the boards have mounting holes, which you would likely have to cover up to use the normal mounting methods.

> Several of the boards, like the mixers, probably need more top ground plane to preserve isolation. I'm not a big fan of putting ground pour everywhere, but in some places it is necessary. Where fencing is needed in the middle of the board, such as the DDS, the ground plane to which it solders should be free of solder mask.

> > Â I'll be more specific. If you take a released SLIM-PWB and have several made by Express, they are SLIMs. If you take a released SLIM-PWB and convert it to another CAD design for some other PWB house to manufacture, it will be a SLIM, but only if the conversion is 100% accurate. Any change to the pwb design negates its status as a "released SLIM".

Thanks for the comments.

I definitely not like rework on these boards (as is pointed out by scotty that errors may occur during this process). However, expressPCB's services are not available for me, also their's prices are really expensive.

I will test the performance of these boards in the following days, and the test results will be updated on my website.

Most of the modifications about these boards are specialized for a kind of enclosure (refer to: http://www.qsl.net/bg6khc/closure1.jpg, http://www.qsl.net/bg6khc/closure.jpg, http://www.qsl.net/bg6khc/closure2.jpg), which costs only U$2-3 for me.

thanks.
BG6KHC
